## Precision Ball & Roller Bearings for Machine Tools Preface

Thank you for your valuable support of **KOYO** products.

Nowadays, there is a pressing demand in the industrial world for sophisticating machine tools in all aspects.

Accordingly, ball & roller bearings for machine tools must be more compact and lightweight and exhibit such features as longer service life, higher performance, and higher reliability. This is made possible only through a wide range of high technologies.

Under these circumstances, we have decided to publish this revised version of the **KOYO** catalog, **Precision Ball & Roller Bearings for Machine Tools**.

In this catalog, we have enriched the contents and added new products.

We are confident that this catalog will be of help to the user in the design of machine tools and in the use of precision rolling bearings.

**JTEKT** continually offers the best technologies, quality, and services, through inspiration from the market and putting efforts into research and technical developments.

We hope that you will be as satisfied with our products and services as you have been in the past.

☆The contents of this catalog are subject to change without prior notice. Every possible effort has been made to ensure that the data listed in this catalogue is correct. However, we can not assume responsibility for any errors or omissions.

Reproduction of this catalog without JTEKT's permission is strictly prohibited.

# CONTENTS

## I. Precision Ball & Roller Bearings

### Technical Descriptions

1. Types and structures of precision ball & roller bearings for machine tools .....	12
2. Selection of bearings .....	14
3. Selection of bearing types .....	15
4. Spindle bearing arrangements .....	16
5. Service life of bearings	
5.1 Rating life of bearings .....	18
5.2 Service life calculation of bearings .....	18
5.3 Dynamic equivalent loads .....	20
5.4 Basic static load rating and static equivalent load .....	23
5.5 Service life of greases .....	24
5.6 Permissible axial loads .....	24
6. Rigidity and preload of bearings	
6.1 Rigidity of bearings .....	25
6.2 Preload of bearings .....	25
7. Limiting speeds of bearings .....	30
8. Lubrication	
8.1 Grease lubrication .....	32
8.2 Oil lubrication .....	33
9. Designing peripheral parts of bearings	
9.1 Tolerances of shafts and housings .....	35
9.2 Limits of chamfer dimensions and fillet radii of shafts and housings .....	36
9.3 Spacers for oil / air lubrication .....	37
10. High Ability angular contact ball bearings .....	42
11. Ceramic bearings for machine tool spindles .....	45

### Bearing Dimension Tables

1. Angular Contact Ball Bearings	
1.1 Types and features of angular contact ball bearings .....	53
1.2 Matched pair angular contact ball bearings .....	54
1.3 Composition of bearing numbers .....	55
1.4 Tolerance of bearings .....	56
1.5 Standard preloads for matched pair angular contact ball bearings .....	58
1.6 Axial load and displacement .....	60
(Bearing Dimension Tables) .....	66
2. Cylindrical Roller Bearings	
2.1 Types and features of cylindrical roller bearings .....	123
2.2 Composition of bearing numbers .....	123
2.3 Tolerance of cylindrical roller bearings .....	124
2.4 Radial internal clearances of cylindrical roller bearings .....	125
(Bearing Dimension Tables) .....	126
3. Angular Contact Ball Bearings for Axial Load	
3.1 Types and features of angular contact ball bearings for axial load .....	137
3.2 Composition of bearing numbers .....	138
3.3 Tolerance of angular contact ball bearings for axial load .....	139
3.4 Standard preloads for high-speed matched pair angular contact ball bearings .....	142
3.5 Axial load and displacement .....	143
(Bearing Dimension Tables) .....	146

<b>4. Tapered Roller Bearings</b>	
4.1 Types and features of tapered roller bearings .....	157
4.2 Composition of bearing numbers ...	157
4.3 Tolerance of tapered roller bearings .....	158
4.4 Axial load and displacement .....	159
(Bearing Dimension Tables) .....	160
<b>5. Support Bearings and Support Bearing Units for Precision Ball Screws</b>	
5.1 Structure and features .....	171
5.2 Composition of identification numbers .....	173
5.3 Tolerance of support bearings for precision ball screws .....	174
5.4 Axial load and displacement .....	174
(Bearing and Bearing Unit Dimension Tables) .....	176

## II. Oil / Air Lubrication System

1. Oil / air lubricator .....	184
2. Air cleaning unit.....	188

## III. Handling of Bearings

1. Handling and mounting of bearings...	192
---	-----

## IV. Examples of Bearing Failures

1. Bearing failures, causes and countermeasures .....	204
---	-----

## V. Supplementary Tables

1. Shaft tolerances.....	208
2. Housing bore tolerances .....	210
3. Numerical values for standard tolerance grades IT .....	212
4. Steel hardness conversion.....	213
5. SI units and conversion factors .....	214
6. Lubrication (discharge) intervals of the oil / air.....	219
7. Specification report.....	220

Bearing types	Cross-sections	Bearing series	Contact angles	Features and descriptions	Page No.		
 Angular contact ball bearings		Standard types	79C 70C 72C	15°	<ul style="list-style-type: none"> <li>Some bearing series support contact angle of 40° (B).</li> </ul>	51	
			70 72	30°			
			Standard types	79CPA 70CPA 72CPA	15°	<ul style="list-style-type: none"> <li>Exhibits superb high-speed performance using an outer ring guided cage.</li> </ul>	82
				HAR9C HAR0C	15°		
				HAR9CA HAR0CA	20°		
			High-speed types	HAR9 HAR0	30°	<ul style="list-style-type: none"> <li>Improvements in high-speed performance are made through the use of balls that have a smaller diameter than standard bearing balls. Also, a large number of balls contributes to higher rigidity.</li> <li>Rolling elements are available in steel and in ceramic.</li> <li>Consult JTEKT, as the HAR000 series can correspond to the non-contact seal.</li> </ul>	106
				3NCHAC9C 3NCHAC0C	15°		
		High-speed types	3NCHAC9CA 3NCHAC0CA	20°	<ul style="list-style-type: none"> <li>Large-diameter balls enable high load-carrying capacity.</li> <li>Ceramic balls realize excellent high-speed performance.</li> </ul>	114	
			3NCHAD0CA	20°			
		Ultra-high-speed types	3NCHAF9CA 3NCHAF0CA	20°	<ul style="list-style-type: none"> <li>These bearings have holes for oil / air lubrication. They are suitable for ultrahigh-speed applications.</li> <li>Ceramic balls realize excellent high-speed performance.</li> </ul>	121	
							
 NN-type double row cylindrical roller bearings		NN30 NN30K	—	<ul style="list-style-type: none"> <li>Bearings with tapered bores (K) are also available for applications using tapered shafts.</li> <li>For radial internal clearance values, use non-interchangeable bearings.</li> </ul>	121		
 NNU-type double row cylindrical roller bearings						NNU49 NNU49K	—
 N-type single row cylindrical roller bearings		N10 N10K	—	<ul style="list-style-type: none"> <li>Bearings with tapered bores (K) are also available for applications using tapered shafts.</li> <li>For radial internal clearance values, use non-interchangeable bearings.</li> <li>This type of bearing produces less heat and has better high-speed performance than double row cylindrical roller bearings.</li> </ul>			

**Table 1. 1(2) Types and structures of precision ball & roller bearings for machine tools**

Bearing types	Cross-sections	Bearing series	Contact angles	Features and descriptions	Page No.
 Double-direction angular contact thrust ball bearings		2344B	60°	<ul style="list-style-type: none"> <li>Placed on the small tapered-bore diameter side of NN30K, or used together with NN30.</li> </ul>	135
		2347B		<ul style="list-style-type: none"> <li>Placed on the large tapered-bore diameter side of NN30K.</li> </ul>	
		2394B	60°	<ul style="list-style-type: none"> <li>Placed on the small tapered-bore diameter side of NNU49K, or used together with NNU49.</li> </ul>	
		2397B		<ul style="list-style-type: none"> <li>Placed on the large tapered-bore diameter side of NNU49K.</li> </ul>	
 High-speed pair-mounted angular contact ball bearings		ACT0DB	30°	<ul style="list-style-type: none"> <li>High-speed bearings of the same bore and outside diameters as double-direction angular contact thrust ball bearings 2344B.</li> </ul>	
		ACT0BDB	40°	<ul style="list-style-type: none"> <li>They are placed on the small tapered-bore diameter side of NN30K.</li> </ul>	
 Tapered roller bearings		329JR 320JR 302JR 322JR	Nominal contact angles: greater than 10° and equal to or less than 17°	<ul style="list-style-type: none"> <li>Metric series single row tapered roller bearings complying with ISO standards.</li> </ul>	155

**2 Support bearings and support bearing units for precision ball screws**

Bearing types	Cross-sections	Bearing series	Contact angles	Features and descriptions	Page No.
 Support bearings for precision ball screws	 Both-side sealed type   Matching example of one-side sealed type	SAC	60°	<ul style="list-style-type: none"> <li>Standard preloads are specified, respectively, for 2-, 3-, and 4-row matched bearings.</li> <li>Flush-ground G-type bearings are also available.</li> <li>The support bearing for precision ball screws can correspond to the type with contact-seal. Consult JTEKT if desiring information about the type with seal and the matching method.</li> </ul>	169
 Support bearing units for precision ball screws		BSU	(60°)	<ul style="list-style-type: none"> <li>Support bearing units consist of a support bearing for precision ball screws (SAC) and a precision housing.</li> <li>Fitting this bearing unit is very simple.</li> </ul>	

## 2. Selection of bearings

In order to select the optimum bearing to realize the intended design of a machine, it is necessary to consider specific operating conditions of the machine, bearing requirements, designs of parts around the bearing, marketability, and cost performance.

**Table 2. 1** specifies the general procedure for selecting a bearing, and operating conditions to be taken into consideration. Note, however, that when selecting a bearing, priority should be given to meeting the most critical requirement rather than following a given procedure.

**Table 2. 1 Procedure for selecting bearings and operating conditions to be taken into consideration**

Selection procedure	Operating condition to be taken into consideration	Related information on bearings	Page No.	
<div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">① Bearing types and arrangements</div> <div style="text-align: center;">↓</div>	<ul style="list-style-type: none"> <li>· Installation space</li> <li>· Magnitude, direction, and types of load applied to bearings</li> <li>· Rotational speeds</li> <li>· Noise/frictional torque</li> <li>· Method of mounting and dismounting</li> <li>· Marketability and cost performance</li> </ul>	<ul style="list-style-type: none"> <li>· Bearing types</li> <li>· Bearing arrangement examples</li> </ul>	<p>15</p> <p>16</p>

<div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">Decision on final specifications of bearing and parts around bearing</div>				

If you wish to consult **JTEKT** about specifications, fill out the supplementary **table 7 "Specification report of bearing for main shaft of machine tool"** on page 220, and contact **JTEKT**.

### 3. Selection of bearing types

When selecting a bearing type, it is of critical importance to fully understand the operating conditions of the bearing.

**Table 3. 1** shows principal items to be considered and how to select a bearing type.

**Table 3. 1 Selection of bearing types**

Items to be considered	How to select a type
<p>① Installation space</p> <p>Bearing can be installed in target equipment</p>	<ul style="list-style-type: none"> <li>When designing a shaft system, critical factors on the whole are shaft rigidity and strength, therefore, shaft diameter, namely, the bore diameter of the bearing is determined first.</li> <li>The installation space determined by types and the dimension series of the bearings used for the spindles of machine tools are shown in <b>Fig. 3. 1</b>. Select the optimum bearing from the types illustrated.</li> </ul>
<p>② Load</p> <p>Load magnitude, type and direction which applied</p> <p>The load capacity of the bearing is expressed in terms of the basic load rating, the value of which is given in the bearing dimension tables.</p>	<ul style="list-style-type: none"> <li>Select the optimum bearing type taking into consideration the magnitude of the load applied to the bearing, whether the load is axial or radial, whether, in the case of axial load, the load is unidirectional or bidirectional, the level of vibration and shock, and other relevant factors.</li> <li>Radial load capacity varies as shown below with the bore diameter remaining the same.</li> </ul> <p>(Small) <math>\xrightarrow{\hspace{10em}}</math> (Large)</p> <p>Angular contact ball bearings    Cylindrical roller bearings    Tapered roller bearings</p>
<p>③ Rotational speeds</p> <p>Bearing types compatible with the machine's operating speed</p> <p>Standard values for rotational speed limits of bearings are expressed in limiting speed given in the bearing dimension tables.</p>	<ul style="list-style-type: none"> <li>Limiting speeds of bearings largely depends not only on the bearing type, but also on other factors such as bearing size, running accuracy, type and materials of the cage, magnitude of load, and lubrication. Select a bearing taking these fully into consideration.</li> <li>In general, angular contact ball bearings and cylindrical roller bearings are often used for high-speed applications.</li> </ul>
<p>④ Running accuracy</p> <p>Bearing types meeting requirements for running accuracy</p> <p>Dimension and running accuracies are standardized by JIS and the like for each bearing type.</p>	<ul style="list-style-type: none"> <li>The spindles of machine tools, which need to rotate with high accuracy, require precision bearings meeting tolerance class 5 or better.</li> <li>In general, angular contact ball bearings and cylindrical roller bearings are used.</li> </ul>
<p>⑤ Rigidity</p> <p>Bearing types meeting the rigidity requirements for machine shaft systems</p> <p>When a load is applied to a bearing, elastic deformation occurs at the contacts between the raceway and rolling elements. The smaller the elastic deformation, the higher the rigidity.</p>	<ul style="list-style-type: none"> <li>In order to improve the machining precision of a machine tool, the rigidity of bearings as well as the rigidity of the shaft should be improved.</li> <li>In general, roller bearings exhibit a high rigidity, while ball bearings exhibit low rigidity. Bearings of the same type and dimensions vary in rigidity with the number of rolling elements and contact angle.</li> <li>The rigidity of a bearing is increased by applying a preload to the bearing (to provide a clearance of a negative value). This method is suitable for angular contact ball bearings and tapered roller bearings.</li> </ul>
<p>⑥ Mounting and dismounting</p> <p>Bearing types should be selected taking into consideration the frequency and method of mounting and dismounting on occasions such as periodic inspection</p>	<ul style="list-style-type: none"> <li>If the bearing is to be mounted and dismounted frequently, cylindrical roller bearings and tapered roller bearings are advantageous, as the inner ring and outer ring are separable.</li> </ul>

**Fig. 3. 1** Installation space determined by types and dimension series of precision rolling bearings for machine tools

## 4. Spindle bearing arrangements

Table 4. 1 presents typical arrangements for spindle bearings for machine tools.

For high-speed spindles, the use of ceramic bearings enables higher speed.

**Table 4. 1(1) Examples of spindle bearing arrangements**

(The  $d_{mn}$  value represents the product of the pitch diameter of ball set  $d_m$  and the rotational speed  $n$ .)

Types	Spindle bearing arrangements	Features	Principal applications
I	 <p>(Front) (Rear)</p> <p>Single row tapered roller bearing 320JR Double row cylindrical roller bearing NN30K</p> <p>Grease lubrication <math>d_{mn}</math> value <math>0.2 \times 10^6</math></p>	<ul style="list-style-type: none"> <li>Both radial and axial loads are accepted by the tapered roller bearing.</li> <li>This arrangement produces high rigidity but is not suitable for high speed operation.</li> <li>In some cases, a double row tapered roller bearing 46C or 46T is used in the front.                             <ul style="list-style-type: none"> <li>46C : two single row bearings combined in an outward arrangement</li> <li>46T : a double cup and two single row of cones constituting an outward arrangement</li> </ul> </li> </ul>	Large lathes General-purpose lathes Milling machines

## 5. Service life of bearings

### 5.1 Rating life of bearings

When a bearing rotates under a load, the surfaces of the inner and outer ring raceways and the surfaces of the rolling elements are constantly subjected to repetitive loads. Even under proper operating conditions this results in scale-like damage (known as flaking) of the surfaces due to fatigue.

The total number of rotations before this damage occurs is known as "(fatigue) service life" of the bearing.

A substantial variation in "(fatigue) service life" occurs even if bearings of the same structure, dimensions, materials, machining method, etc. are operated under the same conditions.

This variation in fatigue, an intrinsic phenomenon to the material, should be examined statistically.

The total number of rotations at which 90% of the same type of bearings individually operated under the same conditions are free of damage caused by rolling fatigue (in other words, service life of 90% reliability), is referred to as "basic rating life of the bearing."

In some cases, however, bearings, when actually mounted and operated on a machine, may become inoperative due to causes other than damage by fatigue (wear, seizure, creep, fretting, brinelling, cracking, etc.).

By giving sufficient consideration to the selection of bearings, installation, lubrication, and the like, it is possible to avoid such causes.

### 5.2 Service life calculation of bearings

#### 5.2.1 Basic dynamic load ratings

The strength of a bearing against rolling fatigue—that is, the basic dynamic load rating representing the bearing load capacity—is the net radial load (in the case of a radial bearing) or central axial load (in the case of a thrust bearing) such that its magnitude and direction are constant and the bearing can attain a basic rating life of 1 million rotations under the condition that the inner ring rotates while the outer ring is stationary (or vice versa).

These are called "basic dynamic radial load rating ( $C_r$ )" or "basic dynamic axial load rating ( $C_a$ )," respectively. Values for these items are given in the bearing dimension tables.

#### 5.2.2 Basic rating life

The relationship among the basic dynamic load rating, the dynamic equivalent load, and the basic rating life is expressed by equation (5. 1).

If a bearing is to be operated at a constant rotational speed, its service life is conveniently expressed in hours as determined by equation (5. 2).

---

(Total number of rotations)

$$L_{10} = \left(\frac{C}{P}\right)^p \dots\dots\dots (5. 1)$$

(Hours)  $L_{10h} = \frac{10^6}{60n} \left(\frac{C}{P}\right)^p \dots\dots\dots (5. 2)$

---

where,

- $L_{10}$  : basic rating life 10<sup>6</sup> rotations
  - $L_{10h}$  : basic rating life h
  - $P$  : dynamic equivalent load N
  - $C$  : basic dynamic load rating N
  - $n$  : rotational speed min<sup>-1</sup>
  - $p$  :  $p=3$  for ball bearings
  - $p=10/3$  for roller bearings
- 

When a bearing is operated with a dynamic equivalent load of  $P$  and a rotational speed of  $n$ , the basic dynamic load rating  $C$  of the bearing, which is suitable for meeting the design service life, is given by equation (5. 3). Thus the bearing dimensions are determined by selecting a bearing from the bearing dimension tables, which meets requirement  $C$ .

---

$$C = P \left( L_{10h} \times \frac{60n}{10^6} \right)^{1/p} \dots\dots\dots (5. 3)$$

---

## [ Reference ] A method for determining the rating life of a bearing in a simplified method

A formula for determining service life, in which a service life coefficient ( $f_h$ ) and speed coefficient ( $f_n$ ) are applied in equation (5. 2), is shown below.

$$L_{10h} = 500 f_h^p \dots\dots\dots (5. 4)$$

Service life coefficient :

$$f_h = f_n \frac{C}{P} \dots\dots\dots (5. 5)$$

Speed coefficient :

$$f_n = \left( \frac{10^6}{500 \times 60 n} \right)^{1/p} \\ = (0.03 n)^{-1/p} \dots\dots\dots (5. 6)$$

Values of  $f_n$ ,  $f_h$ , and  $L_{10h}$  are approximated by the nomograms shown in **Fig. 5. 1**.

### How to use nomograms

#### ■ Operating conditions (example)

- Cylindrical roller bearing  
NN3014K  $C=96.9$  kN
- Rotational speed  
 $n=7\,000$  min<sup>-1</sup>
- Dynamic equivalent load  
 $P=4.9$  kN

#### ① Speed coefficient :

Since  $n=7\,000$   
 $f_n$  reads:  $f_n=0.2$

#### ② Service life coefficient :

$f_h$  is obtained as follows.

$$f_h = f_n \frac{C}{P} = 0.2 \times \frac{96.9}{4.9} = 3.96$$

#### ③ Rating life :

Since  $f_h=3.96$ ,  
 $L_{10h}$  is:  $L_{10h}=49\,000$

### Ball bearing

### Roller bearing

**Fig. 5. 1** Rotational speed ( $n$ ) vs. speed coefficient ( $f_n$ ) and service life coefficient ( $f_h$ ) vs. service life ( $L_{10h}$ )

### 5.3 Dynamic equivalent loads

Bearings are used under different conditions. For example, they are often subjected to a resultant load consisting of radial and axial loads, the magnitudes of which may vary.

Consequently, it is not possible to directly compare the actual load that a bearing receives and the basic dynamic load rating.

In such a case, a calculation is carried out for comparison and examination, in which a load having a constant magnitude and direction, is applied to the bearing center such that it would make the service life of the bearing the same as that resulting from the actual load and rotational speed.

This theoretical load is known as the dynamic equivalent load ( $P$ ).

#### 5.3.1 Calculation of dynamic equivalent load

The dynamic equivalent loads of a radial bearing and a thrust bearing ( $\alpha \neq 90^\circ$ ) receiving a resultant load constant in magnitude and direction is obtained as illustrated below.

$$P = XF_r + YF_a \dots\dots\dots (5.7)$$

where,

$P$  : dynamic equivalent load            N  
 ( For radial bearings,  
 " $P_r$  : dynamic equivalent radial load"  
 and for thrust bearings,  
 " $P_a$  : dynamic equivalent axial load,"  
 respectively, are used. )

$F_r$  : radial load                                N

$F_a$  : axial load                                 N

$X$  : radial load coefficient

$Y$  : axial load coefficient

( Values of  $X$  and  $Y$  are noted  
 in the bearing dimension tables. )

1) If  $F_a/F_r \leq e$  for a single row radial bearing,  $X=1$  and  $Y=0$  are used.

Hence, the dynamic equivalent load will be

$$P_r = F_r.$$

(  $e$  denotes the limit of  $F_a/F_r$ , whose values  
 are listed in the bearing dimension tables. )

2) Application of a radial load to a single row angular contact ball bearing, or tapered roller bearing, produces a component of force ( $F_{ac}$ ) in the axial direction (Fig. 5.2).

Therefore, a pair of bearings are usually used to arrange face-to-face or back-to-back.

The component of force in the axial direction is determined by the following equation.

$$F_{ac} = \frac{F_r}{2Y} \dots\dots\dots (5.8)$$

( Dimensions representing the position of load center are noted in the bearing dimension tables. )

Fig. 5.2 Components of force in axial direction

Table 5.1 (page 21) shows ways of determining the dynamic equivalent load where a radial load and external axial load ( $K_a$ ) are applied to these bearings.

**Table 5. 1 Calculations of dynamic equivalent loads for two opposing single row angular contact ball bearings or tapered roller bearings**

Bearing arrangement		Loading condition	Bearing	Axial load	Dynamic equivalent load
Back-to-back	Face-to-face				
		$\frac{F_{rB}}{2Y_B} + K_a \geq \frac{F_{rA}}{2Y_A}$	Bearing A	$\frac{F_{rB}}{2Y_B} + K_a$	$P_A = XF_{rA} + Y_A \left( \frac{F_{rB}}{2Y_B} + K_a \right)$ Note that $P_A = F_{rA}$ if $P_A < F_{rA}$
			Bearing B	—	$P_B = F_{rB}$
		$\frac{F_{rB}}{2Y_B} + K_a < \frac{F_{rA}}{2Y_A}$	Bearing A	—	$P_A = F_{rA}$
			Bearing B	$\frac{F_{rA}}{2Y_A} - K_a$	$P_B = XF_{rB} + Y_B \left( \frac{F_{rA}}{2Y_A} - K_a \right)$ Note that $P_B = F_{rB}$ if $P_B < F_{rB}$
		$\frac{F_{rB}}{2Y_B} \leq \frac{F_{rA}}{2Y_A} + K_a$	Bearing A	—	$P_A = F_{rA}$
			Bearing B	$\frac{F_{rA}}{2Y_A} + K_a$	$P_B = XF_{rB} + Y_B \left( \frac{F_{rA}}{2Y_A} + K_a \right)$ Note that $P_B = F_{rB}$ if $P_B < F_{rB}$
		$\frac{F_{rB}}{2Y_B} > \frac{F_{rA}}{2Y_A} + K_a$	Bearing A	$\frac{F_{rB}}{2Y_B} - K_a$	$P_A = XF_{rA} + Y_A \left( \frac{F_{rB}}{2Y_B} - K_a \right)$ Note that $P_A = F_{rA}$ if $P_A < F_{rA}$
			Bearing B	—	$P_B = F_{rB}$

**[ Remarks ]** 1. These calculations are applicable where during operation the internal clearance and preload are 0 (zero).  
 2. Radial loads are assumed to be positive even if they are applied in the opposite direction of the arrows shown above.

**5. 3. 2 Mean dynamic equivalent loads for variable loads**

When a load, applied to a bearing, varies in magnitude and direction, it is necessary to obtain a mean dynamic equivalent load that may result in the same service life as would result under actual variation conditions.

Ways of determining the mean dynamic equivalent load  $P_m$  suitable for different variation conditions are shown in **Table 5. 2**, (1) to (4).

In the case when a stationary load and a rotational load are applied simultaneously, as shown in (5), the mean dynamic equivalent load is given by equation (5. 13).

**Table 5. 2 Ways of determining mean dynamic equivalent loads from variable loads**

(1) Stepwise variation	(2) Simple variation	(3) Sine like curve variation
		
$P_m = \sqrt[p]{\frac{P_1^p n_1 t_1 + P_2^p n_2 t_2 + \dots + P_n^p n_n t_n}{n_1 t_1 + n_2 t_2 + \dots + n_n t_n}} \dots (5. 9)$	$P_m = \frac{P_{min} + 2P_{max}}{3} \dots (5. 10)$	$P_m = 0.68 P_{max} \dots (5. 11)$
<p><b>Sine like curve variation (4) (Upper portion of a sine curve)</b></p>	<p><b>Stationary and rotational loads being applied at the same time (5)</b></p>	
		<p><b>Fig. 5. 3 <math>f_m</math> Coefficient</b></p>
$P_m = 0.75 P_{max} \dots (5. 12)$	$P_m = f_m (P + P_u) \dots (5. 13)$	

• In (1) to (4) in Table 5. 2:

- $P_m$  : mean dynamic equivalent load N
- $P_1$  : dynamic equivalent load applied at a rotational speed of  $n_1$  for  $t_1$  hours N
- $P_2$  : dynamic equivalent load applied at a rotational speed of  $n_2$  for  $t_2$  hours N

⋮ ⋮ ⋮

- $P_n$  : dynamic equivalent load applied at a rotational speed of  $n_n$  for  $t_n$  hours N

- $P_{min}$  : minimum dynamic equivalent load N

- $P_{max}$  : maximum dynamic equivalent load N

$\Sigma n_i t_i$  : total number of rotations in a period from  $t_1$  to  $t_i$

$p$  :  $p=3$  for ball bearings

$p=10/3$  for roller bearings

(Reference) The mean rotational speed  $n_m$  is obtained by the following equation.

$$n_m = \frac{n_1 t_1 + n_2 t_2 + \dots + n_n t_n}{t_1 + t_2 + \dots + t_n}$$

• In (5) in Table 5. 2:

- $P_m$  : mean dynamic equivalent load N
- $f_m$  : coefficient (see Fig. 5. 3)
- $P$  : stationary load N
- $P_u$  : rotational load N

## 5. 4 Basic static load rating and static equivalent load

### 5. 4. 1 Basic static load rating

Excessive static load or impact load even at very low rotation causes partial permanent deformation of the rolling element and raceway contacting surfaces. This permanent deformation increases with the load; if it exceeds a certain limit, smooth rotation will be hindered.

The basic static load rating is the static load which responds to the calculated contact stress shown below, at the contact center between the raceway and rolling elements which receive the maximum load.

- Self-aligning ball bearings ... 4 600 MPa
- Other ball bearings ..... 4 200 MPa
- Roller bearings ..... 4 000 MPa

The total extent of contact stress-caused permanent deformation on surfaces of rolling elements and raceway will be approximately 0.000 1 times greater than the rolling element diameter.

The basic static load rating for radial bearings is

specified as the basic static radial load rating, and for thrust bearings, as the basic static axial load rating. These load ratings are listed in the bearing specification table, using  $C_{0r}$  and  $C_{0a}$  respectively.

These values are prescribed by ISO 78/1987 and are subject to change by conformance to the latest ISO standards.

### 5. 4. 2 Static equivalent load

The static equivalent load is a theoretical load calculated such that, during rotation at very low speed or when bearings are stationary, the same contact stress as that imposed under actual loading condition is generated at the contact center between raceway and rolling element to which the maximum load is applied.

For radial bearings, radial load passing through the bearing center is used for the calculation; for thrust bearings, axial load in a direction along the bearing axis is used.

The static equivalent load can be calculated using the following equations.

[Radial bearings]

...The greater value obtained by the following two equations is used.

$$P_{0r} = X_0 F_r + Y_0 F_a \dots\dots\dots (5. 14)$$

$$P_{0r} = F_r \dots\dots\dots (5. 15)$$

[Thrust bearings]

( $\alpha \neq 90^\circ$ )

$$P_{0a} = X_0 F_r + F_a \dots\dots\dots (5. 16)$$

[When  $F_a < X_0 F_r$ ,

the solution becomes less accurate.]

( $\alpha = 90^\circ$ )

$$P_{0a} = F_a \dots\dots\dots (5. 17)$$

where,

$P_{0r}$  : static equivalent radial load N

$P_{0a}$  : static equivalent axial load N

$F_r$  : radial load N

$F_a$  : axial load N

$X_0$  : static radial load factor

$Y_0$  : static axial load factor

(values of  $X_0$  and  $Y_0$  are listed in the bearing specification table.)

### 5. 4. 3 Safety coefficient

The allowable static equivalent load for a bearing is determined by the basic static load rating of the bearing; however, bearing service life, which is affected by permanent deformation, differs in accordance with the performance required of the

bearing and operating conditions.

Therefore, a safety coefficient is designated, based on empirical data, so as to ensure safety in relation to basic static load rating.

$$f_s = \frac{C_0}{P_0} \dots\dots\dots (5. 18)$$

where,

- $f_s$  : safety coefficient (ref. **Table 5. 3**)
- $C_0$  : basic static load rating N
- $P_0$  : static equivalent load N

**Table 5. 3 Values of safety coefficient  $f_s$**

Operating condition		$f_s$ (min.)	
		Ball bearing	Roller bearing
With bearing rotation	When high accuracy is required	2	3
	Normal operation	1	1.5
	When impact load is applied	1.5	3
Without bearing rotation (occasional oscillation)	Normal operation	0.5	1
	When impact load or uneven distribution load is applied	1	2

[ Remark ] For spherical thrust roller bearings,  $f_s \geq 4$ .

### 5. 5 Service life of greases

The previous section explained the fatigue service life of bearings. Spindle bearings for machine tools, however, rarely have a problem of bearing service life caused by load.

When grease lubrication is used, ineffective lubrication may occasionally occur, resulting in bearing failures. It is therefore necessary to give sufficient consideration to selecting the brand and the amount of grease to be used, for given operating conditions.

Refer to "**8. Lubrication of bearings**" for grease lubrication.

### 5. 6 Permissible axial loads

A large axial load may be applied to the bearings for main shafts of machine tools when, for example, tools are changed.

Application of a large axial load to an angular contact ball bearing may cause the contact ellipse formed between the ball and raceway surface to deviate beyond the raceway surface (see **Fig. 5. 4**).

Furthermore, if the stress becomes excessive, the rolling elements and raceway surface may sustain permanent deformation (nicks), possibly resulting in increased runout or vibration.

The smaller one of the following values is defined as the permissible axial load (static). And the permissible axial load (static) for each bearing is shown in the dimension list of the bearings.

- The load generated when the end of the contact ellipse formed between the ball and the raceway reaches the shoulder of the inner or outer ring.
- The load generated when the pressure of the contact surface between the ball and the raceway reaches the standard value calculated based on the actual results.

where,

- $h$  : bearing shoulder height
- $a$  : half length of the contact ellipses' major axis
- $F_a$  : axial load

**Fig. 5. 4 Contact ellipse**

## 6. Rigidity and preload of bearings

### 6.1 Rigidity of bearings

The rigidity of a bearing has a considerable influence on the rigidity of the spindle of the machine tool. The rigidity of a bearing can be improved by the following methods.

- ① Roller bearings, in which line contact is made between the raceway surface and the rolling element, are used when a high radial rigidity is required.
- ② In the case where high axial rigidity is required, stack mounting angular contact ball bearings, are generally used.  
Furthermore, bearings with a large contact angle are used.
- ③ For high-speed and high-rigidity requirements, it is effective to reduce the diameter and increase the number of rolling elements.

It is also possible to improve the rigidity of a bearing by using ceramics (silicon nitride) for the rolling elements which is superior in Young's modulus.

Bearings having ceramic rolling elements also offer improved high-speed performance since their density is lower than that of bearing steel, yielding a small centrifugal force even under high-speed rotation.

- ④ Apply a preload to the bearing.

### 6.2 Preload of bearings

Preloading means setting the inner clearance to be a negative value and loading the bearing after mounting it.

In case of the angular contact ball bearing and tapered roller bearing, an axial load is applied when preloading. And in case of the cylindrical roller bearing, a radial load is applied when preloading.

#### 6.2.1 Objective of preload

- To improve rigidity
- To improve the positioning accuracy in the radial and axial directions, and to improve the running accuracy as well, by minimizing the runout of the shaft
- To reduce smearing by controlling whirl slip, orbital slip, and rotational slip of rolling elements in high-speed rotations
- To prevent noise caused by vibration and resonance

#### 6.2.2 Methods for preloading

There are two major methods for preloading the angular contact ball bearing and tapered roller bearing; position preloading and constant-pressure preloading.

In the position preloading method, the bearing and spacer, whose dimensions are adjusted to the specified values beforehand, are used. In the constant-pressure preloading method, coil springs or disk springs are used to preload the bearing.

Usage examples and comparison of these methods are shown in **Fig. 6.1**.

Also, these preloading methods can be switched over when rotating, and the amount of the preload (load) can be gradually changed in accordance with the speed of the rotation.

**Table 6.1 Methods for preloading**

Position preloading		Constant-pressure preloading	
<p>When applying the same preload, the displacement to load is smaller and the rigidity is higher than when using the constant-pressure preloading method.</p> <p>When rotating at high speed, the use of this method is limited because the preload amount varies depending on the mounting conditions, centrifugal force and temperature rise.</p>		<p>This method is applicable when rotating at high speed because there is less preload variation when rotating than when using the position preloading method, and almost constant preload can be maintained.</p> <p>However, the improvement of the rigidity of the shaft is not as good as when using the position preloading method.</p>	
<p>① A method using matched pair bearings with the preload adjusted.</p>	<p>② A method using a spacer of preadjusted size.</p>	<p>③ A method using a nut or bolt capable of adjusting the amount of preload in the axial direction.</p> <p>(In this case, confirm that the appropriate preload is applied while measuring the starting torque, etc. This method is not suitable for conditions which require high precision, because the bearing tends to tilt easily. In these conditions, methods 1) and 2) are recommended.)</p>	<p>A method using coil springs or disk springs to apply preload.</p> <p>When using the coil springs, place them on the circumference at regular intervals so that the pressure is applied equally.</p>

6. 2. 3 Preload and axial rigidity

Fig. 6. 1 shows the relationship between preload (position preload) and rigidity, namely, axial displacement of a back-to-back arrangement bearing.

Applying a preload  $P$  (by tightening the inner ring in the axial direction), as shown in Fig. 6. 1, results in bearings A and B respectively being displaced by  $\delta_{aA}$ . The clearance between the inner rings  $2\delta_{a0}$  will then become 0 (zero).

When an external axial load  $T$  is applied to these bearings, their resultant displacement as a pair-mounted bearing set can be obtained as  $\delta_a$ .

Fig. 6. 1 Preload diagram for position preloading

[ Reference ] How to determine  $\delta_a$  in Fig. 6. 1

- ① Obtain the displacement curve of bearing A.
- ② Obtain the displacement curve of bearing B: this is the curve symmetrical with respect to the transverse axis and the intersection  $x$  at the preload  $P$ .
- ③ Assuming an external load  $T$ , obtain a line  $x-y$  on the transverse axis passing through  $x$ . By parallel displacement of line  $x-y$  along the displacement curve of bearing B, the intersection  $y'$  passing through the displacement curve of bearing A is obtained.
- ④  $\delta_a$  is determined as the distance between the lines  $x'-y'$  and  $x-y$ .

Fig. 6. 2 shows the relationship between preload and rigidity when a constant-pressure preload is applied to the same pair-mounted bearing as shown in Fig. 6. 1.

Since the rigidity of the spring is negligible in this case, the rigidity of the bearing is approximately equal to that of a single bearing given a preload  $P$ .

Fig. 6. 2 Preload diagram of constant-pressure preloading

Comparison of axial rigidity of the position preloading and the constant-pressure preloading is shown in Fig. 6. 3.

Fig. 6. 3 Comparison of axial rigidity

## 6. 2. 4 Amount of preload

If the amount of preload to the bearing is increased, the rigidity is improved.

However, as the load is applied to the bearing, the life may become shorter and abnormal heat may be generated, resulting in serious failure, including early damage, seizure, etc.

Also, in case of position preloading, the amount of preload varies depending on the mounting conditions, including fitting of the bearing, the centrifugal force generated during the operation and the temperature rise.

## 6. 2. 5 Variation of position preloading due to fitting and rotation

### 1) Preload in mounting the bearing

The angular contact ball bearing is shown as a model in Fig. 6. 4a.

In case of the bearing for the main shaft of a machine tool, for which the inner ring is usually rotated, the interference fit is employed for the inner ring, and the clearance fit is employed for the outer ring. However, the diameter of the inner ring raceway will expand due to interference, and the axial clearance changes as shown in Fig. 6. 4b, resulting in the increase in the amount of preload.

Furthermore, if the inner ring is tightened by the shaft nut, etc., the width of the inner ring and the spacer will shrink, resulting in increase in preload.

This is the preload generated when the bearing is mounted.

### 2) Change of preload during rotation

During rotation, the preload is changed by centrifugal force and temperature rise.

When rotating, the inner ring is affected by the centrifugal force and the raceway expands. Due to this expansion, the preload increases as shown in Fig. 6. 4c.

Influence of temperature rise is described below.

When rotating, the temperature of the bearing increases and the components expand because of rotation resistance, stirring resistance generated by the lubricant, and other external factors.

The temperature increase of the inner ring and the rolling elements is larger than that of the outer ring, which radiates heat easily. Therefore, the internal clearance changes because of the expansion as shown in Fig. 6. 4d, and the preload is increased.

Also, the temperature difference is generated between the outer ring and the housing, and the outer ring becomes hotter than the housing, reducing the clearance of the fitting surface of the outer ring. If the clearance of the fitting surface of the outer ring is too small, the fitting of the outer ring becomes interference fitting because of the temperature difference, and the internal clearance changes due to the shrinkage of the raceway of the outer ring, increasing the preload as shown in Fig. 6. 4e.

As a result, it is also important to take into consideration the case where the housing cools off excessively.

Fig. 6. 4a Bearing before mounting

Fig. 6. 4b Change of dimension due to inner ring interference

Fig. 6. 4c Change of dimension due to centrifugal expansion of inner ring raceway

Fig. 6. 4d Change of dimension due to heat expansion

Fig. 6. 4e Change of dimension due to shrinkage of outer ring raceway

$A_{s0}$	: initial stand-out value (The sum of the stand-out value of a pair of bearings is the size of the clearance for which the preload is provided.)
$T$	: interference of inner ring
$\delta_{IRt}$	: expansion of inner ring raceway due to inner ring interference
$\delta_{Ast}$	: change of bearing stand-out value due to inner ring interference
$\delta_{IRc}$	: centrifugal expansion of inner ring raceway
$\delta_{Asc}$	: change of bearing stand-out value due to centrifugal expansion of inner ring raceway
$\delta_{IRte}$	: heat expansion of inner ring raceway
$\delta_{ORte}$	: heat expansion of outer ring raceway
$\delta_{Bte}$	: heat expansion of rolling element
$\delta_{Aste}$	: change of bearing stand-out value due to temperature rise of each component
$\delta_{Aso}$	: change of bearing stand-out value due to shrinkage of outer ring raceway
$\delta_{As}$	: total of change of stand-out value due to mounting conditions and rotation

6. 2. 6 Selecting preload and fitting

To maintain the initial performance of the bearing and use it in stable condition, it is necessary to select an ideal preloading method and preload amount considering the use conditions as well as the mounting conditions.

Especially, when using the bearing at high speed, it is indispensable to select an ideal preload, taking into consideration the preload change, the pressure between the raceway and the rolling elements

generated by centrifugal force, and the factors which cause spin slide of the angular contact ball bearing.

The standard preload amount of each bearing is shown in the table of bearing dimensions. Also, the interferences of the bearings for main shafts in standard use condition are shown in **Figs. 6. 2** and **6. 3** (page 26).

Consult JTEKT for detailed information about preloads and fittings when using the bearings at high speed with value  $d_m n$  set at  $80 \times 10^4$  or more or with a heavy load of  $C_r/P_r < 13$ .

[ Remark ] Consult JTEKT for specific operating conditions (high-speed rotation, outer ring rotation, heavy load, etc.).

## 7. Limiting speeds of bearings

The rotational speed of a bearing is restricted chiefly by temperature increases caused by frictional heat generated within the bearing. When a speed limit is reached, it becomes impossible to continue operation due to seizure and the like.

The permissible rotational speed of a bearing represents the value of limiting speed at which the bearing can continue operation without causing seizure-generated temperatures.

Accordingly, the limiting speed differs with bearing types, dimensions, accuracy, lubrication methods, quality and quantity of lubricant, shape and material of cages, loading conditions (including amount of preload), etc.

The limiting speed for grease lubrication or oil (oil / air) lubrication of bearings are given in their dimension tables.

These values are the limiting speed that are applicable where a bearing of a standard design is operated under normal loading conditions ( $C_r/P_r \geq 13$ ,  $F_a/F_r \leq \text{approx. } 0.2$ ).

- $C_r$  : basic dynamic load rating
- $P_r$  : dynamic equivalent load
- $F_r$  : radial load
- $F_a$  : axial load

Spindle bearings for machine tools are used in one of 2-, 3-, or 4-row combinations. The limiting speed of a stack mounting bearing is lower than that of a single row bearing.

The speed coefficients are shown in **Table 7. 1**. In this table, the correlations between the preload amounts and the matching methods of the bearings mounted to the shafts with position preloading are shown. Differences are made due to the heat radiation and the variation in the preload amount of each bearing.

Where a lubricant can efficiently remove the heat generated in the bearing, the limiting speed of a bearing will be greater than those given in the bearing dimension tables.

If the rotational speed of a bearing exceeds 80% of the value listed in the bearing dimension tables, careful consideration should be given to the amount of preload, lubrication method, lubricant, distance between the bearings, etc. Consult JTEKT.

**Table 7. 1 Speed coefficients**

Matching method	Prefix	Preload in mounting			
		Preload S	Preload L	Preload M	Preload H
	DB	0.85	0.80	0.65	0.55
	DBB	0.80	0.75	0.60	0.45
	DBD	0.75	0.70	0.55	0.40

\* The speed coefficients vary depending on the distance between the bearings.

## 8. Lubrication

Lubrication is a critical issue for bearings, on which their performance greatly depends.

The suitability of a lubricant and lubrication method has great influence on the performance of a bearing.

Lubrication plays the following roles.

- Lubrication of each part of the bearing reduces wear and friction.
- Removes heat in the bearing generated by friction and other causes.
- Extends the service life of bearings by constantly forming an adequate oil film on the rolling contact surfaces.
- Rust prevention and dust proofing for bearings

Lubrication is very important for spindle bearings of machine tools since such bearings require a low temperature increase under high-speed operation.

Relationships between the quantity of lubricant and power loss and between the quantity of lubricant and the temperature increase of the bearing are shown in **Fig. 8. 1**. Relationships between the viscosity of lubricant and power loss and between the viscosity of lubricant and the temperature increase of the bearing are shown in **Fig. 8. 2**.

**Fig. 8. 1** Relationships between lubricant quantity and power loss and between lubricant quantity and the temperature increase of the bearing

**Fig. 8. 2** Relationships between viscosity of lubricant and power loss and between viscosity of lubricant and the temperature increase of the bearing

The quantity of lubricant needed to meet the low temperature increase requirement lies in zone A where the quantity of oil is small so the agitation loss is low, and zone B in which a large quantity of oil transfers heat from the bearing to the outside. Regarding the viscosity of lubricant, those which are of relatively low viscosity are suitable for meeting the above-mentioned requirement.

Note, however, that an excessively small quantity of oil or excessively low viscosity will not maintain a suitable lubricant film during operation, and further induce the chances of seizure.

For bearing lubrication methods, grease, oil / air, or oil mist lubrication is recommended in zone A in **Fig. 8. 1**, and jet lubrication, in zone B.

**Table 8. 1** shows a comparison of features for various lubrication methods. It is important to select a lubrication method and a lubricant to best suit to the machine specifications.

**Table 8. 1** Comparison of features of different lubrication methods

○ : advantageous  
 △ : somewhat disadvantageous  
 × : disadvantageous

Lubrication method	Grease lubrication	Oil / air lubrication	Oil mist lubrication	Jet lubrication

Temperature increase of bearing	△	○	△	○
High-speed reliability	×	○	△	○
Power loss	○	○	○	×
Volume occupied by lubricator	○	△	△	×
Environmental contamination	○	△	×	△
Service life of lubricant	×	○	○	○

## 8.1 Grease lubrication

Grease lubrication is most usually employed because it requires no special lubricator and the use of a relatively simple housing structure is sufficient.

However, to meet machine tool bearing requirements (high-speed operation, low temperature increase, and long service life of sealed grease), the following should be taken into consideration.

### 8.1.1 Types of grease

In order to meet the low level temperature increase requirement of a bearings during operation, a grease low in base oil viscosity is suitable.

In general, grease NLGI 2 in consistency and approximately 10-30 mm<sup>2</sup>/s in base oil viscosity is often used for spindle bearings of machine tools. In cases where bearings are subjected to high loads, a grease with a base oil viscosity of approximately 100 mm<sup>2</sup>/s, and an extreme-pressure agent may be used to secure lubricant film during operation.

**Table 8. 2** shows grease for spindle bearings of machine tools.

### 8.1.2 Sealing device

For spindle bearings of machine tools, it is important to use a reliable sealing device to prevent mixing of coolant, chips, wear particle of drive belt, gear lubricant, and so forth.

Where grease lubrication is adopted, contaminants have a great influence on the service life of a bearing.

An example of sealing device for grease lubrication is shown in **Fig. 8. 3**.

**Fig. 8. 3** Example of sealing device for grease lubrication (labyrinth seal)

**Table 8. 2** Grease for spindle bearings of machine tools (representative examples)

Grease name	Manufacturer	Thickener	Base oil	Base oil viscosity mm <sup>2</sup> /s (40°C)	Application
Beacon 325	Exxon Mobil	Lithium	Diester	12	High-speed operation, low temperature
Maltemp PS 2	Kyodo oil	Lithium	Diester+mineral oil	14	
Isoflex NBU 15	NOK klüber	Barium complex	Diester+mineral oil	20	
Stabrag NBU 8 EP	NOK klüber	Barium complex	Mineral oil	105	High-load operation, wear resistance
Alvania No. 2	Showa shell sekiyu	Lithium	Mineral oil	130	

## 8.2 Oil lubrication

### 8.2.1 Oil / air lubrication

In this lubrication method, a small amount of oil of a specified quantity is supplied intermittently to each bearing by compressed air.

A schematic drawing of an oil / air lubrication system is shown in Fig. 8. 4.

Fig. 8. 4 Oil / air lubrication system

Since oil / air lubrication has features as shown below, it has become popular in many high-speed spindle.

1. Compared with grease lubrication, oil / air lubrication allows bearings to meet the low temperature increase and high-speed operation requirements (see Fig. 8. 5).
  2. Compared with oil mist lubrication, oil / air lubrication is simple to adjust the quantity of oil with a high degree of accuracy. This leads to a high reliability for bearings during high-speed operation.
- In addition, unlike oil mist lubrication, oil / air lubrication is free from environmental contamination and also reduces oil consumption.

3. Compared with jet lubrication, oil / air lubrication suppresses power losses of bearings (see Fig. 8. 6). This feature saves space because a smaller drive motor and cooling unit can be used. The structure of the main shaft can also be simple and compact.

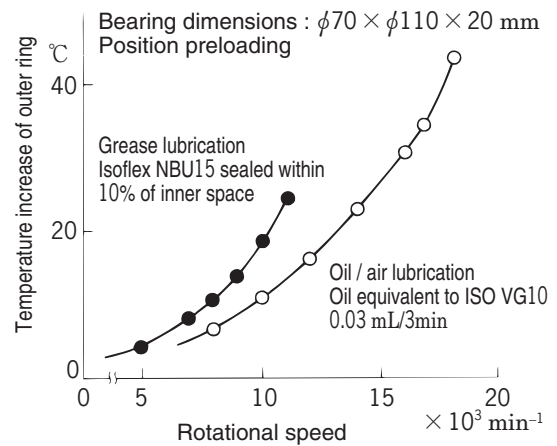

Fig. 8. 5 Comparison of the temperature increase between oil / air lubrication and grease lubrication

Fig. 8. 6 Comparison of power loss between oil / air lubrication and jet lubrication

In order to take advantage of oil / air lubrication features, JTEKT has produced oil / air lubricators and air cleaning units, of which we have special knowhow and have shipped to many customers.

Consult JTEKT for the application of the oil / air lubrication systems.

For details of the oil / air lubricator and air cleaning unit, see "II. Oil / Air Lubrication System."

Refer to Table 9. 4 on page 37 for information about the dimensions of the spacers for oil / air lubrication.

Refer to Supplementary table 6 on page 219 for information about the blow intervals of the oil / air.

### 8. 2. 2 Oil mist lubrication

Similar to oil / air lubrication, oil mist lubrication supplies a small quantity of oil to each bearing by compressed air.

Fig. 8. 7 shows an oil mist lubrication system.

Fig. 8. 7 Oil mist lubrication system

The cost of oil mist lubrication is relatively low. The high-speed performance attained by this method is better than by grease lubrication.

To obtain maximum performance from this method, due consideration should be given to the following.

#### 1. Oil quantity settings

The quantity of oil is set by the rate at which the oil mist generator produces oil drops. Since the rate of oil turned to mist depends on the type of oil, air pressure, flow rate, etc., it is important to determine the amount of oil drops required after the characteristics of the whole system have been sufficiently understood.

#### 2. Distribution of mist to several bearings

In general, a single oil mist generator is used to distribute the mist to several bearings.

Each bearing should be checked to see if it is supplied with an adequate quantity of oil.

#### 3. Installation of suitable nozzle(s)

The nozzle converts dry mist into wet mist suitable for lubrication of bearings and supplies mist to the inside of bearings.

For reliable operation, the nozzle design should be given sufficient consideration.

A well-designed nozzle reduces the quantity of oil so that contamination by oil mist will also be reduced.

### 8. 2. 3 Jet lubrication

Jet lubrication is a method in which a large quantity of lubricant is injected at a high velocities through the bearing side to lubricate and cool the bearing simultaneously.

Fig. 8. 8 shows a jet lubrication system.

Fig. 8. 8 Jet lubrication system

Owing to its high reliability for high-speed operation, the jet lubrication is often applied to such bearings designed for high-speed and high-temperature operation, for example, gas turbine engines. Also, jet lubrication is sometimes employed for the high-speed spindles of machine tools. If this is the case, give due consideration to the following points.

1. Use oil of extremely low viscosity of approximately  $2 \text{ mm}^2/\text{s}$  to restrain power loss and temperature increase.
2. To improve cooling efficiency, set the velocity of the lubricant ejected from the nozzle to at least 20% of the peripheral speed of the outer surface of the inner ring, thereby allowing more oil to pass through the bearing.  
Installing several nozzles on the circumference for a larger quantity of oil is also effective to some degree.
3. A pump or similar device should be used to discharge oil smoothly. For this reason, the discharge port should be as large as possible to ensure a smooth discharge of oil.  
After discharge, the lubricant should be cooled with a heat exchanger of adequate capacity in order to minimize temperature changes.  
It is also essential to maintain clean lubricant by installing an appropriate filter, ensuring an airtight oil tank, and so forth.

## 9. Designing peripheral parts of bearings

### 9.1 Tolerances of shafts and housings

When the inner and outer rings of a bearing are mounted on a shaft and a housing with a certain interference, the shapes of the shaft and housing tend to influence the raceway surface of the bearing leading to a change in running accuracy.

Therefore, shafts and housings need to be finished

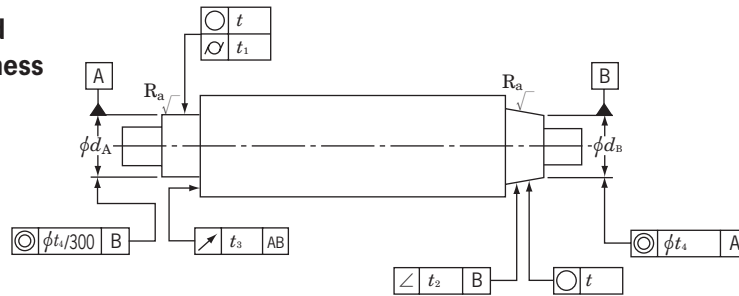

to maximum possible precision.

Recommended values for tolerances and surface roughness of shafts and housings are shown in

**Tables 9.1** and **9.2**.

Refer to "III. Handling of Bearings" for details about handling and mounting of the bearings.

**Table 9.1 Tolerances and surface roughness of shafts**

Unit :  $\mu\text{m}$

Shaft diameter (mm)		Roundness( $\odot$ )		Cylindricity( $\odot$ )		Inclination( $\sphericalangle$ )		Deflection( $\nearrow$ )		Coaxiality( $\odot$ )		Roughness

500	630	8	5.5	8	5.5		16	30	22	1.6	0.8

- [ Remarks ]
1. Tolerances, symbols, and reference planes for housings comply with ISO/R1101.
  2. When determining the tolerance in relation to the permissible accuracy of shapes, the housing bore diameters  $D_A$  and  $D_B$  are used as reference dimensions.

9.2 Limits of chamfer dimensions and fillet radii of shafts and housings

[ Remark ]

An imaginary arc with a radius of  $r$  (min) is defined as being tangent to both the side face of the inner ring and the bore surface of the bearing; or to both the side face of outer ring and the outside surface of the bearing. Although an exact shape is not specified for chamfered surfaces, the outline in the axial plane shall not extend beyond the imaginary arc.

$r$  : dimension for chamfering inner and outer rings

$r_1$  : dimension for chamfering the front and the likes of the inner and outer rings

Table 9.3 Limits of chamfer dimensions and fillet radii of shafts and housings

## 10. High Ability angular contact ball bearings

High Ability angular contact ball bearings are optimized for use on machine-tool spindles. They excel in high-speed performance and rapid acceleration/deceleration, and are especially superior

in ultrahigh-speed applications when used with oil / air lubrication. Even with grease lubrication, these bearings are superior to conventional products in high-speed applications.

### 10.1 Types and applications

High Ability angular contact bearings are available in the varieties listed in **Table 10. 1**, all of which differ in structure and rolling-element material.

Select the type that is best suited for the application.

**Table 10. 1 High Ability bearing types and principal applications**

Principal applications	Type	Specification		
		Bearing dimension series	Contact angle	Material of rolling element
High-speed, high-rigidity type	Type R 	10 19	15° 20° 30°	Steel or ceramics
High-speed, high load-rating type	Type C 	10 19	15° 20°	ceramics
Ultrafast, low-noise type for oil / air lubrication	Type D 	10	20°	ceramics
Extremely ultrafast type for oil / air lubrication	Type F 	10 19	20°	ceramics

### 10.2 Features

● **20 to 30% reduction in temperature increase (compared with JTEKT's conventional products)**

JTEKT has conducted various tests and analyses and developed elaborate machining techniques to improve the performance of bearings used with machining tool spindles. The result is a substantial reduction in frictional heat generated in bearings rotating at a high speed.

● **1.2- to 1.5-time increases in speed limits (compared with JTEKT's conventional products)**

Speed limits have been extended through re-designing for high-speed rotation and heat reduction. Use of ceramic balls as rolling elements enables additional high-speed rotation.

● **Improved high-speed performance achieved by position preloading**

Low increases in temperature during operation ensure reduced changes in preload. Preload can be given by position preloading even at high speeds, which has been hitherto unavailable with conventional systems. The result is high-precision machining with stability.

● **Conventional bearings easily replaced**

Dimensions of High Ability bearings conform to ISO standards. Replacement of conventional bearings with High Ability bearings requires minimal geometry changes of the present spindle or housing.

**Fig. 10. 1 Lubrication method for Type D**

High Ability Type D bearings are designed for oil / air lubrication. Their inner rings have an oiling groove to ensure lubrication on the rolling contact surface for improved lubrication reliability.

**Fig. 10. 2 Lubrication method used in Type F**

The oiling port in Type F is provided at its outer ring to ensure improved lubrication reliability on the guide ways of the cage. High Ability Type F bearings deliver the best high-speed performance.

### 10.3 Performance

High Ability bearings exhibit their maximum performance when used in pairs or when more than two units are combined and when preload is given by position preloading. Shown below is the operating performance of High Ability bearings with preload given by position preloading.

#### 1) Performance of Types R and C

Fig. 10. 3 compares relationships between rotational speed and increases in bearing temperature of Types R and C and conventional high-precision bearings.

High Ability bearings exhibit smaller temperature increases and higher speed limits than conventional bearings whether grease lubrication or oil / air lubrication is applied.

As shown in Fig. 10. 4, this type has excellent anti-seizure characteristics with small quantity of lubricant oil in comparison with a conventional type. Thus, the quantity of the lubricant oil can be reduced.

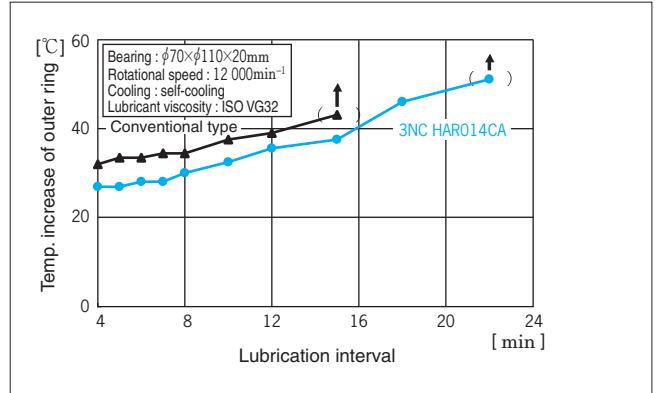

Fig. 10. 4 Comparison of seizure limit oil quantity of Type R and conventional type

High Ability bearings also allow the possible change in lubrication of the spindle from oil / air to grease.

Fig. 10. 5 shows an evaluation example.

Fig. 10. 3 Comparison of increases in bearing temp.

Fig. 10. 5 Comparison of high-speed performance achieved by grease lubrication

Type R high ability ceramic ball bearing and grease lubrication exhibits better high-speed performance than conventional bearings using oil / air lubrication.

If steel balls are used, Type R with grease lubrication exhibits high-speed performance equal to or better than conventional bearings with oil / air lubrication.

2) Performance of Type D

Fig. 10. 6 compares the high-speed performance of Types D and R.

Fig. 10. 6 Comparison of increases in the bearing temp. of Types R and D

Also, Type D causes little wind roar when the bearing is rotating, and is effective in reducing the noise of the spindle device and the air consumption. (Figs. 10. 7 and 10. 8)

Fig. 10. 7 Comparison of noise by Types R and D

Fig. 10. 8 Comparison of air quantity of Type D and conventional type

3) Performance of Type F

Fig. 10. 9 shows an evaluation example of the Type F bearing operated with a preload given by constant pressure preloading. The maximum rotational speed achieved in this test, or 54 000  $\text{min}^{-1}$ , equals  $3.3 \times 10^6$  in  $d_m n$  value.

Fig. 10. 9 Temp. increases in Type F bearing

The oiling port in the outer ring provides sufficient lubrication to achieve a substantial reduction of friction on cage riding land. This lubrication method ensures excellent stability against rapid acceleration or deceleration during operation.

Fig. 10. 10 Operating pattern of type F involving rapid acceleration and deceleration

## 11. Ceramic bearings for machine tool spindles

Compared with bearing steel, ceramics [silicon nitride ( $\text{Si}_3\text{N}_4$ )] has superior properties such as light weight and high elasticity.

One of the advantages of ceramics when used as a material for bearings is a reduction in the slip of rolling elements caused by centrifugal force and gyroscopic moments under high-speed rotation. Ceramic material is highly effective for meeting the low temperature increase requirements of the bearing.

Other advantages include improved rigidity and improvements in seizure life and grease service life. Ceramic bearings, although varying depending on operating conditions, allow approximately 30% to 50% improvement in speed as compared with steel bearings.

### 11.1 Ceramic bearing structures and types

There are three types of ceramic bearings differing in their combinations of ceramic parts. Select the most suitable one from **Table 11.1** according to the machine tool specifications.

**Table 11.1 Ceramic bearing structures and types**

Codes, types, and structures of ceramic bearings			
Code <sup>1)</sup>	3NC	6NC	NC
Description	Rolling element : ceramics	Inner ring : ceramics Rolling element	Inner and outer rings : ceramics Rolling element (Full-ceramic)
Angular contact ball bearing			
Cylindrical roller bearing			

Note 1) A code is placed before a basic bearing number.

### 11.2 Properties of ceramics ( $\text{Si}_3\text{N}_4$ )

Sintered in a high temperature and high-pressure gas atmospheric condition (HIP), ceramics (silicon nitride) has many superior properties such as heat resistance, light weight, low coefficient of linear expansion, and a high elastic modulus.

**Table 11.2** shows a comparison of properties with ceramics and bearing steel.

**Table 11.2 Comparison of mechanical properties**

Item	Unit	Ceramics ( $\text{Si}_3\text{N}_4$ )	Bearing steel (SUJ2)
Heat resistance (in the air)	°C	800	120
Density	$\text{g/cm}^3$	3.2	7.8
Coefficient of linear expansion	$\text{K}^{-1}$	$3.2 \times 10^{-6}$	$12.5 \times 10^{-6}$
Vickers' hardness	HV	1 300~2 000	700~800
Young's modulus	GPa	320	208
Poisson's ratio	—	0.29	0.3
Thermal conductivity	$\text{W}/(\text{m}\cdot\text{K})$	20	41.9~50.2
Corrosion resistance	—	Good	Not good
Magnetism	—	Non-magnetic material	Ferromagnetic material
Electrical conductivity	—	Not applicable (insulant)	Applicable (electric conductor)
Bonding form of material	—	Covalent bond	Metallic bond

### 11.3 Load ratings of ceramic bearings

**JTEKT** has adopted the following values as a standard for load ratings of ceramic bearings. These values are determined from a number of experiments and their results.

- Dynamic load rating :  
Dynamic load rating of steel bearings ( $C$ ) $\times 1.0$  or greater

- Static load rating :  
Static load rating of steel bearings ( $C_0$ ) $\times 1.0$

The load applied to a spindle bearing for a machine tool is generally very small as compared with bearing load ratings. Accordingly, it is rare that a bearing reaches its fatigue service life or brinelling occur in its raceway surfaces.

Sufficient care, however, should be taken to ensure that no impact load is applied to the bearing during handling and operation.

11.4 Sample test data of ceramic bearings

1) High-speed performance of bearings

Ceramic is superior to bearing steel in high-speed rotation performance because it has lower density and linear expansion coefficient.

■ Comparison with steel bearing (1)

Fig. 11.1 Comparison of Angular contact ball bearing

■ Comparison with steel bearing (2)

Fig. 11.2 Comparison of cylindrical roller bearing

■ High-speed performance (1)

Fig. 11.3 High speed performance with grease lub.

■ High-speed performance (2)

Fig. 11.4 High speed performance with oil / air lub.

The 6NC type hybrid ceramic bearings, whose balls and inner ring are both made of ceramic, are superior in high-speed performance to the 3NC type.

In addition, the low-torque 6NC type bearings exhibit lower power losses at high rotational speeds.

■ High-speed performance (3)

Fig. 11.5 Comparison of 3NC type and 6NC type hybrid ceramic bearings

Since ceramics and steel have different coefficients of linear expansion, Young's moduli, and Poisson's ratios, care should be taken when fitting for mounting a 6NC type hybrid ceramic bearing on a shaft is selected.

Consult JTEKT.

2) Rigidity of bearing

Since ceramics have a greater Young's modulus than bearing steel, the rigidity of a ceramic bearing is higher than that of a steel bearing.

Fig. 11.6 Comparison of axial displacement

3) Changes in shaft dimensions

Compared with steel bearings, ceramic bearings have higher rigidity and lower temperature increase, thus reducing the risk of changes in shaft dimensions.

Fig. 11.7 Comparison of displacement at shaft end

4) Fatigue service life and seizure life of bearings

Ceramic bearings are superior to steel bearings in both seizure life and fatigue service life.

■ Seizure life test results (1)

# 1. Angular contact ball bearings

The angular contact ball bearing can receive a radial load, unidirectional axial load, or a combination of the above loads.

There are four different contact angles to choose from when angular contact ball bearings are considered: 15° (contact angle symbol: C), 20° (CA), 30° (A: to be omitted), and 40° (B) (see Fig. 1. 1).

Of these types, the 15° (contact angle symbol: C), 20° (CA) and 30° (A) bearings are usually used for spindle of machine tools.

The greater the contact angle, the higher the axial rigidity, and the smaller the contact angle, the more advantageous for high-speed rotations.

Fig. 1. 1 Contact angles of angular contact ball bearings

## 1. 1 Types and features of angular contact ball bearings

Standard angular contact ball bearings				High Ability angular contact ball bearings			
7900C	7000C 7000	7200C 7200	7900CPA 7000CPA 7200CPA	HAR900C HAR900CA HAR900 HAR000C HAR000CA HAR000	HAC900C HAC900CA HAC000C HAC000CA	HAD000CA	HAF900CA HAF000CA
				<p>*The bearing numbers of the HAC, HAD and HAF type products begin with the prefix "3NC," because they have ceramic balls as standard components.</p>			
				<p>*Consult <b>JTEKT</b>, as the HAR000 series can correspond to the non-contact seal.</p>			

Fig. 1. 2 Types and series of angular contact ball bearings

### 1) Standard angular contact ball bearings

7900C  
7000C, 7000 series  
7200C, 7200

The standard cage is of the ball-guided type and is made from polyamide resin.

7900CPA, 7000CPA, 7200CPA series

- The cages of these bearings are of the outer ring-guided type and are made from reinforced phenolic resin. This type of cage enables superior high-speed performance.
- Bearings that can be disassembled into an outer ring, cage and ball assembly and inner ring are also available.

### 2) High Ability angular contact ball bearings

HAR900C, HAR900CA, HAR900  
HAR000C, HAR000CA, HAR000 High rigidity type  
HAC000C, HAC000CA, HAC900C  
HAC900CA High load-rating type  
HAD000CA, HAF900CA, HAF000CA Ultra-high speed type

- The High Ability angular contact ball bearings are optimized for use on high-speed machine tool spindles. They are available in three types: high rigidity type, high load-rating type, and ultrahigh-speed type. (The ultrahigh-speed type is used with oil / air lubrication.)
- The standard contact angle of these bearings is 20°. The high rigidity type products are also available with a contact angle of 15° and 30°. The high load-rating type products are also available with a contact angle of 15°.
- These bearings have ceramic balls and an outer ring-guided cage made from reinforced phenol resin as standard components.  
Steel-ball products and ball-guided cage products are also available to suit your needs.

## 1.2 Matched pair angular contact ball bearings

Angular contact ball bearings are used in matched pair, or in combinations of more than two bearings. **Table 1. 1** shows combination types and symbols for angular contact ball bearings.

**Table 1. 1 Combination types and symbols for angular contact ball bearings**

Combination types and symbols for angular contact ball bearings			
Matched pair	 Back-to-back Suffix : DB	 Face-to-face Suffix : DF	 Tandem Suffix : DT
	 Suffix : DBD	 Suffix : DFD	 Suffix : DTD
	 Suffix : DBB	 Suffix : DFF	
Matched stack	 Suffix : DBT	 Suffix : DFT	

[Remark] ----- indicates the direction of the "V" mark.

Matched pair angular contact ball bearings are adjusted to a preset amount of preload and axial clearance.

The standard preloads are divided into 4 classes : slight preload (symbol : S), light preload (L), medium preload (M), and heavy preload (H). **Table 1. 4** (page 58) shows amounts of standard preloads.

### Cautions for assembly

(Combination mark)

(Mark indicating position of maximum eccentricity)

### Type G bearings

The type G bearing has both sides machined (flush-ground) to obtain the same stand-out between the inner and outer rings (see **Fig. 1. 3**).

This makes it possible to select any desired combination(s) from **Table 1. 1**.

**Fig. 1. 3 Flush-ground type G bearings**

- Examples of identification numbers of type G bearings
  - 7010GL : Adjustment is made so that any combination of two or more bearings presents light preload (preload symbol : L).
  - 7010GL×2 : Adjustment is made so that any combination of this set of two bearings presents light preload (preload symbol : L).

- ① A "V" mark is put on the outside surfaces of the outer rings of matched pair or matched stack angular contact ball bearings, to indicate their combination mode. Combine them in such a way that the marks on the outer ring form a "V".
- ② Chamfered edges of the inner and outer rings are marked with a circle "○", which shows the position of maximum eccentricity.

Mount bearings so that the "○" marks on the inner and outer rings are opposite (180°) to the position of maximum eccentricity of the shaft or housing. By doing so, maximum running accuracy is obtained.

### 1. 3 Composition of bearing numbers (angular contact ball bearings)

FG : molded cage made of polyamide resin  
 FT : machined cage made of reinforced phenolic  
 FY : machined cage made of copper alloy

**Spacer number/symbol**

No specified : If no spacer is provided.  
 /27 : spacer with lubrication hole, 27 mm in nominal width  
 A : spacer not provided with lubrication hole (symbol A is not used if the spacer has a lubrication hole.)

**Preload symbol\* or clearance symbols**

(\*In some cases, a symbol denoting the specific preload is used.)  
 S : slight preload      CS : clearance  
 L : light preload      CY : negative clearance (preload)  
 M : medium preload    (CS5 : The mean value of the clearance is 5µm.)  
 H : heavy preload

(For amount of preload, see **Table 1. 4** (page 58).)

**Matched pair or stack symbol**

DB : back-to-back  
 DF : face-to-face  
 DT : tandem

For suffixes that denote bearings which consist of three or four bearings, see **Table 1. 1** (page 54).  
 G : Type G bearing (flush-ground bearing)

# 1. Angular contact ball bearings

## 1.4 Tolerance of bearings

The tolerance of the precision angular contact ball bearing is compliant with permissible dimensional deviations and limits of classes 5, 4, and 2 as specified in JIS B 1514 for radial bearings (tapered roller bearings not included).

Permissible dimensional deviations and limits of radial bearings are shown in **Table 1. 2**.

**Table 1. 3** (page 57) shows **JTEKT's** special permissible dimensional deviations (K5) used to facilitate multi-row combinations (K5 is used for the bore diameter of the inner ring and the outside diameter of the outer ring).

**Table 1. 2(1) Permissible dimensional deviations and limits of angular contact ball and cylindrical roller bearings**

**(1) Inner ring**

$S_d$  : Perpendicularity of inner ring face with respect to the bore

$S_{ia}$  : Axial runout of assembled bearing inner ring

- [Notes] 1) Tolerance class 4 is applied to bearings of diameter series 0, 1, 2, 3, and 4.  
 2) Applied to angular contact ball bearings.  
 3) Applied to individual bearing rings manufactured for matched pair or stack bearings.  
 4) Class 5 tolerance complies with JIS; class 4 tolerance is **JTEKT** standard.

[Remark] Values in italics comply with **JTEKT** standards.

$d$  : nominal bore diameter  
 $D$  : nominal outside diameter  
 $B$  : nominal bearing width

180	250	-1	-5	-1	-4

$d$  : nominal bore diameter  
 $D$  : nominal outside diameter

[Note] 1) K5 denotes specially formulated JTEKT standards for the purpose of minimizing individual differences in performance, which may occur as a result of fitting stack-mounted to bearings.

**1. 5 Standard preloads for matched pair angular contact ball bearings**

Back-to-back and face-to-face matched pair bearings are often used under a preload. By applying a preload to a bearing, the following effects are realized.

- 1 ) The rigidity of a bearing can be improved.
- 2 ) Running accuracy is improved.
- 3 ) Abnormal noise caused by vibration and resonance is prevented.

A greater preload results in higher bearing rigidity. However, such preload also influences other parameters of the bearing : service life, temperature, frictional torque, etc. Therefore, it is important to select an adequate preload, taking into consideration the rotational speed and lubrication conditions.

**JTEKT** offers 4 types of preset preloads, slight preload (S), light preload (L), medium preload (M), and heavy preload (H). This will enable the user to select any desired preload suitable for individual applications (see **Table 1. 4**).

As a guide for selecting the preload, light or medium preload is used for spindles of grinding machines, while medium or heavy preloads are used for spindle of lathes and milling machines.

**Table 1. 4(1) Standard preloads for matched pair angular contact ball bearings**

(S : slight preload; L : light preload; M : medium preload; H : heavy preload) Unit : N

1. 6 Axial load and displacement (angular contact ball bearings)

Fig. 1. 4 shows relationships between axial load and displacement of KOYO angular contact ball bearings.

The graphs indicate that the greater the contact angle of a bearing, the smaller the axial displacement

(high rigidity).

The displacement curve of duplex bearings under a given preload is determined by the method shown in Fig. 6. 1 on page 26.

(1) 7900C, 7900CPA series (contact angle : 15°)

(2) 7000C, 7000CPA series (contact angle : 15°)

(3) 7000 series (contact angle : 30°)

(4) 7200C, 7200CPA series (contact angle : 15°)

[Remarks] 1. For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(1) on page 37.  
2. For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H
$\odot \ominus$	DB	0.85	0.80	0.65	0.55
$\odot \odot \ominus \ominus$	DBB	0.80	0.75	0.60	0.45
$\odot \odot \ominus$	DBD	0.75	0.70	0.55	0.40

\*Speed coefficients also vary depending on the distance of bearings.

1. Angular contact ball bearings

7000C series

Contact angle 15°

Static equivalent load  $P_0 = X_0 F_r + Y_0 F_a$

Contact angle	Single row/Tandem		Back-to-back/Face-to-face	
	$X_0$	$Y_0$	$X_0$	$Y_0$
15°	0.5	0.46	1	0.92

Note that in the case of single row or tandem, assume  $P_0 = F_r$  if  $P_0 < F_r$ .

Dynamic equivalent load  $P = X F_r + Y F_a$

Contact angle	$i f_0 F_a / C_{Or}$	$e$	Single row/Tandem				Back-to-back/Face-to-face				
			$F_a / F_r \leq e$		$F_a / F_r > e$		$F_a / F_r \leq e$		$F_a / F_r > e$		
			X	Y	X	Y	X	Y	X	Y

[ Remarks ] 1. For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(1) on page 37.  
2. For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H
$\odot \odot$	DB	0.85	0.80	0.65	0.55
$\odot \odot \odot \odot$	DBB	0.80	0.75	0.60	0.45
$\odot \odot \odot$	DBD	0.75	0.70	0.55	0.40

\*Speed coefficients also vary depending on the distance of bearings.

1. Angular contact ball bearings

7200 series

Contact angle 30°

Static equivalent load  $P_0 = X_0 F_r + Y_0 F_a$

Contact angle	Single row/Tandem		Back-to-back/Face-to-face	
	$X_0$	$Y_0$	$X_0$	$Y_0$
30°	0.5	0.33	1	0.66

Note that in the case of single row or tandem, assume  $P_0 = F_r$  if  $P_0 < F_r$ .

Dynamic equivalent load  $P = X F_r + Y F_a$

Contact angle	e	Single row/Tandem				Back-to-back/Face-to-face			
		$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$		$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$	
		X	Y	X	Y	X	Y	X	Y
30°	0.80	1	0	0.39	0.76	1	0.78	0.63	1.24

- [ Remarks ] 1. For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(1) on page 37.  
2. For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H
$\odot \ominus$	DB	0.85	0.80	0.65	0.55
$\odot \odot \ominus \ominus$	DBB	0.80	0.75	0.60	0.45
$\odot \odot \ominus \odot$	DBD	0.75	0.70	0.55	0.40

\*Speed coefficients also vary depending on the distance of bearings.

1. Angular contact ball bearings

7200CPA series

Contact angle 15°

Static equivalent load  $P_0 = X_0 F_r + Y_0 F_a$

Contact angle	Single row/Tandem		Back-to-back/Face-to-face	
	$X_0$	$Y_0$	$X_0$	$Y_0$
15°	0.5	0.46	1	0.92

Note that in the case of single row or tandem, assume  $P_0 = F_r$  if  $P_0 < F_r$ .

Dynamic equivalent load  $P = X F_r + Y F_a$

Contact angle	$i f_0 F_a / C_{0r}$	$e$	Single row/Tandem				Back-to-back/Face-to-face			
			$F_a / F_r \leq e$		$F_a / F_r > e$		$F_a / F_r \leq e$		$F_a / F_r > e$	
			X	Y	X	Y	X	Y	X	Y
15°	0.178	0.38			1.47		1.65		2.39	
	0.357	0.40			1.40		1.57		2.28	
	0.714	0.43			1.30		1.46		2.11	
	1.07	0.46			1.23		1.38		2.00	
	1.43	0.47	1	0	1.19	1	1.34	0.72	1.93	
	2.14	0.50			1.12		1.26		1.82	
	3.57	0.55			1.02		1.14		1.66	
	5.35	0.56			1.00		1.12		1.63	
	7.14	0.56			1.00		1.12		1.63	

1) For  $i$ , use 2 for DB & DF and 1 for single & DT.

Boundary dimensions (mm)					Bearing No.	Basic load ratings (kN)		Factor $f_0$	Limiting speeds ( $\text{min}^{-1}$ )		Load center (mm) $a$	Interspace volume ( $\text{cm}^3/\text{row}$ )	(Refer.) - [ Remarks ]
- Boundary dimensions of this bearing are the same as those of the 7900 series.
  - For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(2) on page 38.
  - For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

- [ Remarks ]
- Boundary dimensions of this bearing are the same as those of the 7000 series.
  - For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(2) on page 38.
  - For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

- [ Remarks ]
- Boundary dimensions of this bearing are the same as those of the 7900 series.
  - For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(2) on page 38.
  - For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{Or} \times 2$
3-row	$C_r \times 2.16$	$C_{Or} \times 3$
4-row	$C_r \times 2.64$	$C_{Or} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H
$\odot \ominus$	DB	0.85	0.80	0.65	0.55

- [ Remarks ] 1. Boundary dimensions of this bearing are the same as those of the 7900 series.  
 2. For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(2) on page 38.  
 3. For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

- [ Remarks ]
- Boundary dimensions of this bearing are the same as those of the 7000 series.
  - For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(2) on page 38.
  - For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H

- [ Remarks ]
- Boundary dimensions of this bearing are the same as those of the 7000 series.
  - For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(3) on page 39.
  - For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H
	DB	0.85	0.80	0.65	0.55
	DBB	0.80	0.75	0.60	0.45
	DBD	0.75	0.70	0.55	0.40

\*Speed coefficients also vary depending on the distance of bearings.

1. Angular contact ball bearings

High Ability Ceramic bearings

3NCHAC000CA series

Contact angle 20°

Static equivalent load  $P_0 = X_0 F_r + Y_0 F_a$

Contact angle	Single row/Tandem		Back-to-back/Face-to-face	
	$X_0$	$Y_0$	$X_0$	$Y_0$
20°	0.5	0.42	1	0.84

Note that in the case of single row or tandem, assume  $P_0 = F_r$  if  $P_0 > F_r$ .

Dynamic equivalent load  $P = X F_r + Y F_a$

Contact angle	e	Single row/Tandem				Back-to-back/Face-to-face			
		$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$		$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$	
		X	Y	X	Y	X	Y	X	Y
20°	0.57	1	0	0.43	1	1	1.09	0.70	1.63

- [ Remarks ]
- Boundary dimensions of this bearing are the same as those of the 7000 series.
  - For the dimensions of the spacers for oil / air lubrication, refer to Table 9. 4(5) on page 40.
  - For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

Basic load ratings in case of multiple-row combination bearing

	Basic dynamic load ratings	Basic static load ratings
2-row	$C_r \times 1.62$	$C_{0r} \times 2$
3-row	$C_r \times 2.16$	$C_{0r} \times 3$
4-row	$C_r \times 2.64$	$C_{0r} \times 4$

Speed coefficients in case of multiple-row combination bearing

Combination types	Combination symbols	Preload when mounting			
		Preload S	Preload L	Preload M	Preload H
⊗ ⊗	DB	0.85	0.80	0.65	0.55
⊗ ⊗ ⊗ ⊗	DBB	0.80	0.75	0.60	0.45
⊗ ⊗ ⊗ ⊗ ⊗ ⊗	DBD	0.75	0.70	0.55	0.40

\*Speed coefficients also vary depending on the distance of bearings.

These bearings are useful only with oil / air lubrication. Please use with lubricating spacers as shown below.

## 2. Cylindrical roller bearings

The cylindrical roller bearing has high radial rigidity and is suitable for high-speed rotation through an arrangement of many rollers and a line contact which is made between the rollers and raceways.

The bores of cylindrical roller bearings are either cylindrical or tapered. With a bearing having a tapered bore, its radial internal clearance can be set with ease to a given value by adjusting the extent to which the bearing is pushed onto the shaft.

### 2.1 Types and features of cylindrical roller bearings

The cylindrical roller bearing is divided into two types: double row and single row bearings. Both having outer ring which is separable from the inner to facilitate mounting and dismounting from shaft and housing (see Fig. 2. 1).

#### 1) Double row cylindrical roller bearings

The double row cylindrical roller bearing is classified into the NN30 and NNU49 series.

Some of these bearings have a lubrication groove and holes provided at the center of the outside surface of the outer rings in order to attain a sufficient supply of lubricant to the inside of the bearing (the suffix W is added).

#### 2) Single row cylindrical roller bearings

Single row cylindrical roller bearings for the spindles of machine tools are often selected from the N10 series.

The bore and outside diameters of the N10 series are the same as those of the NN30: double row cylindrical roller bearing series.

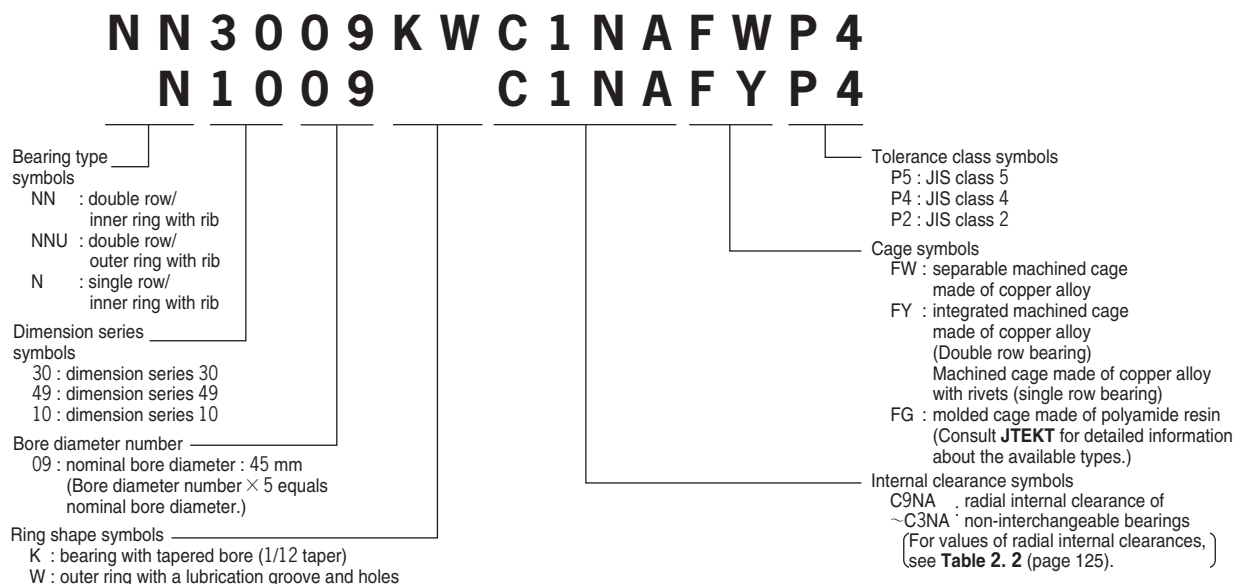

Fig. 2. 1 Types and series of cylindrical roller bearings for machine tool spindles

### 2.2 Composition of bearing numbers (cylindrical roller bearings)

#### For ceramic bearings

**3NCN1009C1NAFY P4**

Ceramic bearing

2.3 Tolerance of cylindrical roller bearings

1) Boundary dimension and running accuracies

The tolerance of precision cylindrical roller bearings is compliant with permissible dimensional deviations and limits of classes 5, 4, and 2 as specified in JIS B 1514 for radial bearings (tapered roller bearings not included).

Permissible dimensional deviations and limits to boundary dimension and running accuracies are shown in **Table 1. 2** on page 56.

2) Permissible dimensional deviations and limits for tapered bores

The dimensional deviations and limits for tapered bores of radial bearings of class 0 only are specified in JIS B 1514.

**JTEKT** has formulated special standards for dimensional deviations and limits for tapered bores of radial bearings of classes 5, 4, and 2 (see **Table 2. 1**).

**Table 2. 1 Dimensional deviations and limits for tapered bores of radial bearings (classes 5, 4, and 2)**

Theoretical tapered bore

Tapered bore with single plane mean bore diameter deviation

Unit : μm

Nominal bore diameter <i>d</i> (mm)		$\Delta_{dmp}$				$\Delta_{d1mp} - \Delta_{dmp}^{1)}$		$V_{dsp}^{2)}$				
		Class 5		Classes 4, 2		Classes 5, 4, 2		Diameter series 9		Diameter series 0		—
over	up to	upper	lower	upper	lower	upper	lower	Class 5	Class 4	Class 5	Class 4	Class 2
								max.		max.		max.
18	30	+10	0	+ 6	0	+ 3	0	6	5	5	4	2.5
30	50	+12	0	+ 8	0	+ 3	0	8	6	6	5	2.5
50	80	+15	0	+ 9	0	+ 5	0	9	7	7	5	4
80	120	+20	0	+10	0	+ 6	0	10	8	8	6	5
120	180	+25	0	+13	0	+ 8	0	13	10	10	8	7
180	250	+30	0	+15	0	+ 9	0	15	12	12	9	8
250	315	+35	0	+18	0	+10	0	18	15	14	11	—
315	400	+40	0	+23	0	+12	0	23	18	18	14	—

[ Notes ] 1) Permissible dimensional deviation for the taper angle is  $4^{\circ}46'18.8''^{+26''}_0$

2) Applied to all radial planes of tapered bores.

[ Remarks ] 1. **Scope** These values are applied to the tapered bores with a reference taper ratio of 1/12.

2. **Symbols for quantities**  $d_1$ : reference diameter at theoretical large end of tapered bore  $d_1 = d + \frac{1}{12}B$

$\Delta_{dmp}$ : single plane mean bore diameter deviation at theoretical small end of tapered bore

$\Delta_{d1mp}$ : single plane mean bore diameter deviation at theoretical large end of tapered bore

$V_{dsp}$ : single plane bore diameter variation

$B$ : nominal inner ring width

$\alpha$ :  $\frac{1}{2}$  of the nominal taper angle of tapered bore

$$\alpha = 2^{\circ}23'9.4''$$

$$= 2.38594^{\circ}$$

$$= 0.041643 \text{ rad}$$

## 2.4 Radial internal clearances of cylindrical roller bearings

In order to minimize variations in the running accuracy of machine tool spindles, the values of the radial internal clearance should be same as those of special radial internal clearance of non-interchangeable bearings.

**Table 2. 2** shows values of non-interchangeable radial internal clearances for cylindrical roller bearings.

Since the inner and outer rings of cylindrical roller bearings for spindles of machine tools are not interchangeable, care should be taken when using them.

**Table 2. 2 Values of radial internal clearances for cylindrical roller bearings**

**(1) Bearings with cylindrical bores**

### 3. Angular contact ball bearings for axial load

JTEKT produces double direction angular contact thrust and high-speed matched pair angular contact ball bearings to receive the axial loads from spindles of machine tools.

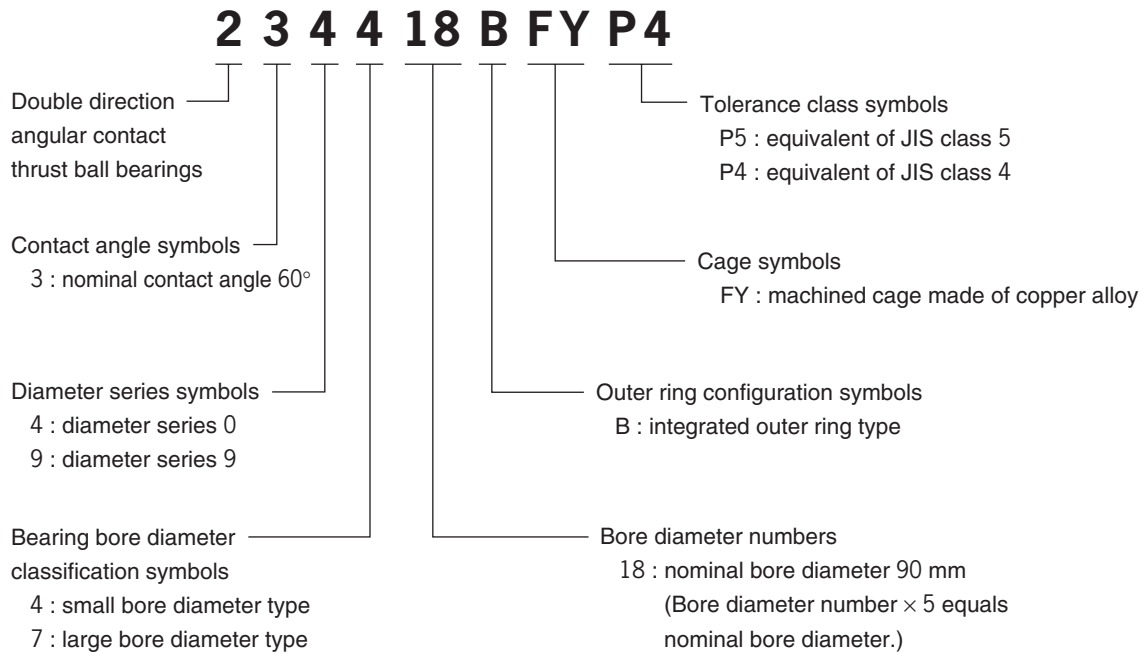

#### 3.1 Types and features of angular contact ball bearings for axial load

Table 3.1 Types and features of angular contact ball bearings for axial load

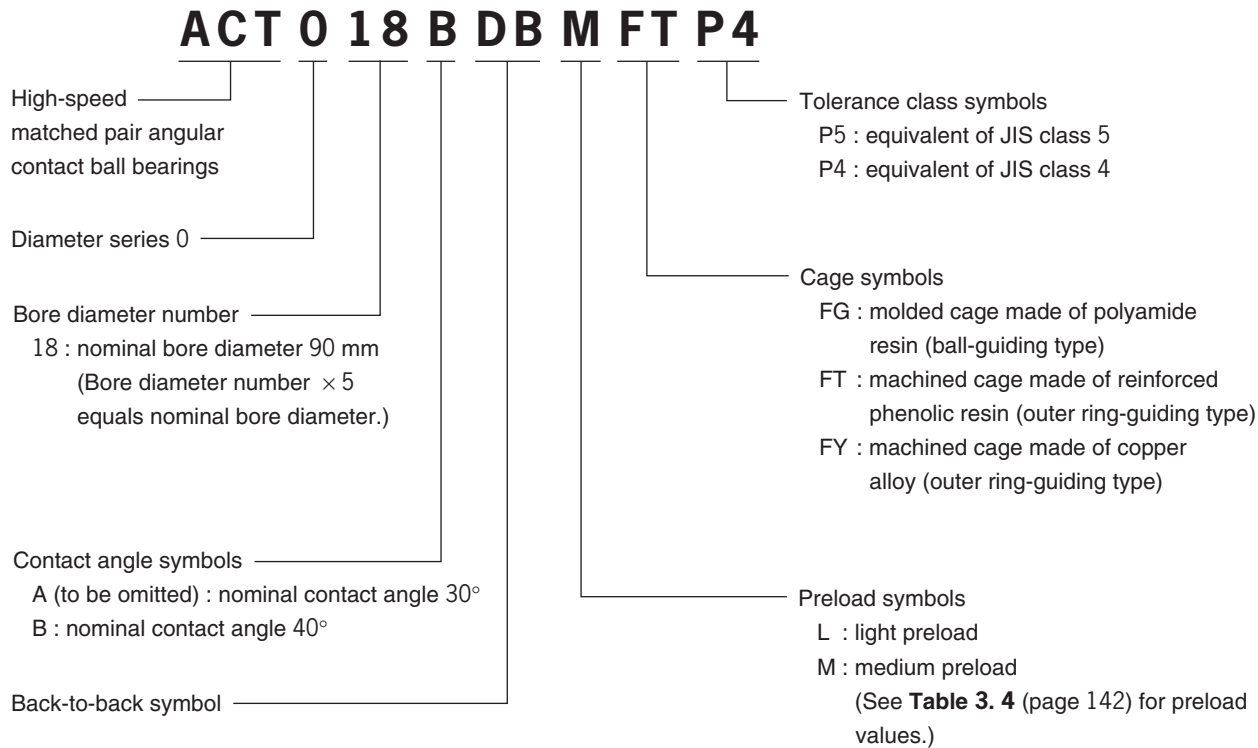

Type	Double direction angular contact thrust ball bearings	High-speed matched pair angular contact ball bearings		To combine with double row cylindrical roller bearings Remark: These bearings are used primarily in combination with double row cylindrical roller bearings for radial load. Combinations are as shown below.
				
Diameter series				
0	2344 B	ACT 0 DB	ACT 0 BDB	Placed next to the small tapered bore diameter side of NN30K, or used in tandem with NN30 (cylindrical bore).
	2347 B	—	—	Placed next to the large tapered bore diameter side of NN30K.
9	2394 B	—	—	Placed next to the small tapered bore diameter side of NNU49K, or used in tandem with NNU49 (cylindrical bore).
	2397 B	—	—	Placed next to the large tapered-bore diameter side of NNU49K.
Features	<ul style="list-style-type: none"> <li>• Axial load can be applied in both directions, and the rigidity in the axial direction is high.</li> <li>• Bearings having greater contact angles are more suitable where rigidity is a priority, and those having smaller contact angles are more appropriate where high-speed performance is a priority.</li> </ul>	<ul style="list-style-type: none"> <li>• Negative tolerances on the outside diameters are used to permit axial load only.</li> <li>• Having small contact angles, these are suitable for high-speed rotations.</li> <li>• These bearings are interchangeable with 2344 B series.</li> </ul>		
Interchangeability	 <p>Example of mounting in tandem with 2344 B</p> <p>Example of mounting in tandem with ACT 0 DB or ACT 0 BDB</p> <p>Since the combined width "2B" of ACT 0 DB and ACT 0 BDB is equal to dimension "C<sub>1</sub>" of 2344 B, it is not necessary to change shaft and housing dimensions. Changing the width of spacer ① is sufficient.</p>			

3.2 Composition of bearing numbers (angular contact ball bearings for axial load)

Double direction angular contact thrust ball bearings

High-speed matched pair angular contact ball bearings

### 3.3 Tolerance of angular contact ball bearings for axial load

The tolerance of double direction angular contact thrust ball bearings is shown in **Table 3.2**.  
The tolerance of high-speed matched pair angular contact ball bearings is shown in **Table 3.3** (page 140

and 141).  
The tolerance of these bearings complies with **JTEKT** standards Classes 5 and 4 (equivalent of JIS Classes 5 and 4).

**Table 3.2 Permissible dimensional deviations and limits to double direction angular contact thrust ball bearings (JTEKT standards)**

**(1) Inner ring and assembled bearing width**

Unit :  $\mu\text{m}$

Nominal bore diameter $d$ (mm)		$\Delta_{dmp}$ or $\Delta_{ds}$ <sup>1)</sup>				Actual bearing width deviation $\Delta_{Ts}$		Inner ring width variation $V_{Bs}$		Perpendicularity of inner ring face with respect to the bore $S_d$		Axial runout of assembled bearing inner ring $S_{ia}$	
		Class 5		Class 4		Classes 5, 4		Class 5	Class 4	Class 5	Class 4	Class 5	Class 4
over	up to	upper	lower	upper	lower	upper	lower	max.		max.		max.

[ Notes ] 1) The small bore diameter type bearing is placed next to the small tapered-bore diameter side of the NN30K, or used in tandem with NN30.  
The large bore diameter type bearing is placed next to the large tapered-bore diameter side of NN30K.  
2) The dimension E<sub>w</sub> is used as a reference for the ball set outside diameter.

3. Angular contact ball bearings for axial load

239400B series  
239700B series

Contact angle 60°

## 4. Tapered roller bearings

The tapered roller bearing is a bearing in which tapered rollers (truncated conical rollers) are inserted between the outer ring and inner ring. The rollers are guided by the inner ring back face rib (see **Fig. 4. 1**).

A radial load and an axial load can be simultaneously applied to the tapered roller bearing. This bearing has high rigidity.

In addition, tapered roller bearings allow easy adjustments of preload.

**Fig. 4. 1 Structure of tapered roller bearing**

Since the single row tapered roller bearing can receive only a unidirectional axial load, a pair of single row bearings are mounted apart and facing each other, or they are often used in a face-to-face or back-to-back arrangement.

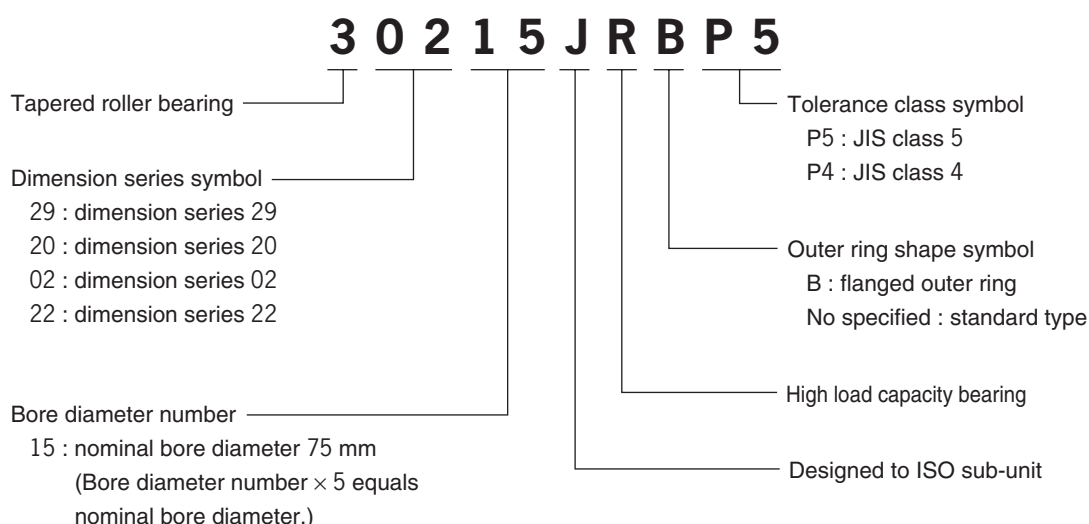

### 4. 1 Types and features of tapered roller bearings

Two types of tapered roller bearings are available for machine tools: the single row tapered roller bearing (auxiliary symbol: JR) and the tapered roller bearing with flanged outer ring (auxiliary symbol: B) (see **Table 4. 1**).

**Table 4. 1 Types and features of tapered roller bearings for machine tools**

Types	Features
Tapered roller bearing with J designation  ISO sub-unit specifications	Bearings whose basic numbers are followed by "J" are made to the ISO sub-unit specifications. Consequently, inner ring assemblies and outer rings, if given the same bearing number, are interchangeable on an international level. Reference: The symbol R denotes high load capacity bearings.
Tapered roller bearing with flanged outer ring 	This bearing allows easy positioning in axial direction using a simple housing structure.

### 4. 2 Composition of bearing numbers (metric series tapered roller bearings)

## 4. Tapered roller bearings

### 4.3 Tolerance of tapered roller bearings

The tolerance of the tapered roller bearing is compliant with permissible dimensional deviations and limits of classes 5 and 4 as specified in JIS B 1514 for tapered roller bearings.

Permissible dimensional deviations and limits to tapered roller bearings are shown in **Table 4. 2**.

**Table 4. 2 Permissible dimensional deviations and limits to metric tapered roller bearings**

[ Note ] 1) The bearing number of a tapered roller bearing with a flanged outer ring contains the auxiliary symbol B.  
Example 32004JRB

4. Tapered roller bearings

30200JR series

Dynamic equivalent load  $P = XF_r + YF_a$

$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$	
X	Y	X	Y
1	0	0.4	$Y_1$

Static equivalent load  $P_0 = 0.5F_r + Y_0F_a$

Note that if  $P_0 < F_r$ , it is assumed that  $P_0 = F_r$ .  
For  $e$ ,  $Y_1$ , and  $Y_0$ , use values given in the table.

## 5. Support bearings and support bearing units for precision ball screws

### 5.1 Structure and features

#### Support bearings for precision ball screws

The SAC type support bearings are angular contact thrust ball bearings specifically for supporting the screw shafts of precision ball screws (see Fig. 5. 1).

The bearings supporting the precision ball screws correspond to the type with contact seal.

Consult JTEKT for details about the type with contact seal and the pair patterns.

Both-side sealed type

Matching example of one-side sealed type

Fig. 5. 1 Structure of support bearings for precision ball screws

These bearings have many, small-diameter balls and thick section inner and outer rings.

The contact angle of these bearings is 60° enabling a high axial load and a certain degree of radial load to be applied simultaneously.

#### 1) Features of support bearings for precision ball screws

- High rigidity  
Has higher rigidity against axial load than conventional standard bearings (see Fig. 5. 2).
- Compact and lightweight  
Since this bearing eliminates the need for an additional radial bearing or thrust bearing, it allows a compact surrounding design, thereby contributing to a reduction in the weight of the total system.
- High precision  
A high-precision bearing suitable for precision ball screws.
- Preload adjustments not required  
Preload is preadjusted to ensure an adequate preload after mounting. As a result, complicated adjustments are not required during mounting.
- Low torque  
Requires lower friction torque than the tapered roller bearing or thrust roller bearing.

Fig. 5. 2 Relationship between axial load and displacement (comparison between support bearings and other bearings)

\*The axial displacements shown above are values of the single-row bearings not preloaded.

#### 2) Matched pair or stack support bearings

Table 5. 1 Types and suffixes of support bearings

Type and suffix of support bearing	
Combination of two	<p>Suffix DB                      Suffix DF</p>
Combination of three	<p>Suffix DFD</p>
Combination of four	<p>Suffix DFF</p>

- [ Remarks ]
1. A "V" mark is put on the outside surfaces of the outer rings of matched pair and stack bearings to indicate their combination type. For handling precautions of the type G bearing, refer to the bearing dimension table "1. 2 Matched pair angular contact ball bearings."
  2. Type G bearings are also manufactured, which enable any desired combinations. For descriptions of the type G bearing, refer to the bearing dimension table "1. 2 Matched pair angular contact ball bearings."

**Support bearing units for precision ball screws**

The support bearing unit for precision ball screws is a unit product combining the SAC type support bearing and a housing machined to a high precision.

**Fig. 5. 3 Series and structures of support bearing units for precision ball screws**

**1) Types of matched pair or stack bearing**

**Table 5. 2 Types of matched pair or stack bearing**

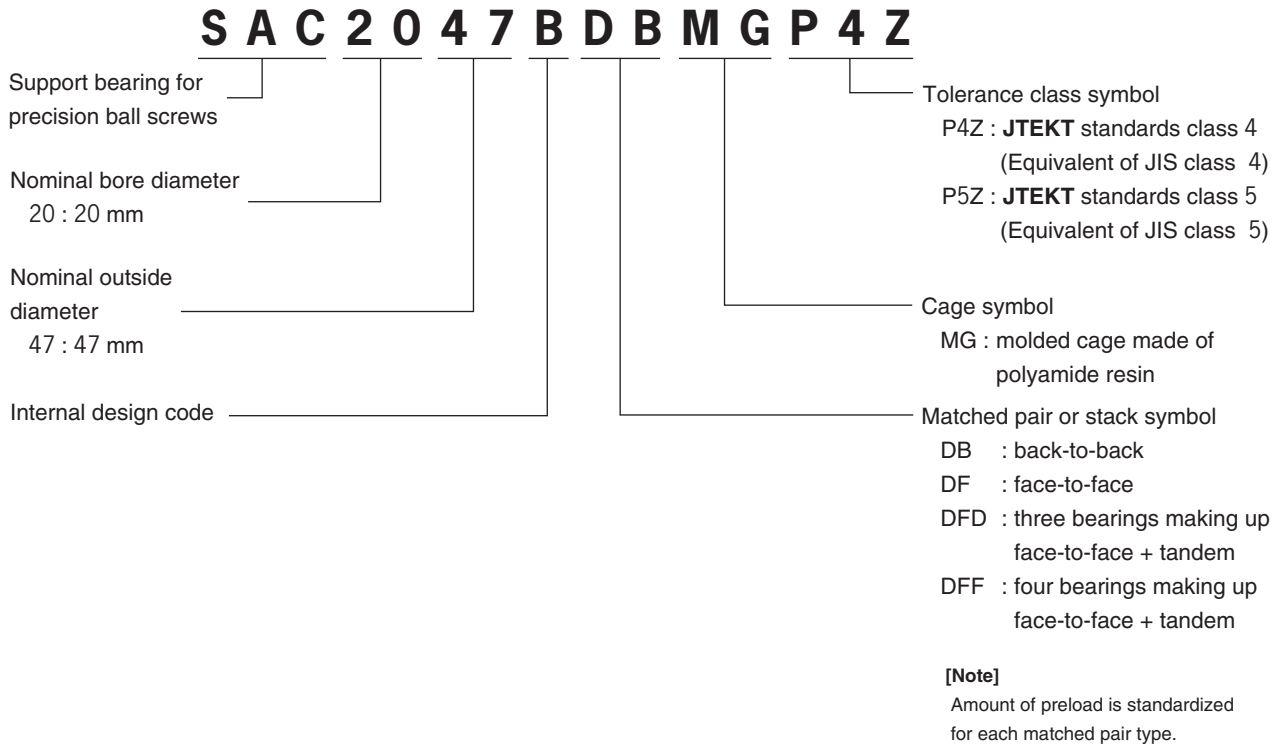

Type and symbol	
Combination of two bearings	<p>(Suffix : DF)</p>
Combination of three bearings	<p>(Suffix : DFD)</p>
Combination of four bearings	<p>(Suffix : DFF)</p>

**2) Features of support bearing units for precision ball screws**

- Simple mounting work  
This is a unit product consisting of a bearing where the preload is adjusted and an adequate quantity of grease is sealed within the bearing, and is mounted in a compact housing.  
Thus the support bearing unit can be easily mounted on a machine.
- Excellent dust-proof performance  
Having a high-performance built in oil seal the support bearing unit, with low torque operation, is excellent in dust-proof performance.
- Capability of coping with any desired design  
In addition to the standard products listed in the dimension tables, **JTEKT** manufactures support bearing units to meet the support structures of various ball screws.  
Consult **JTEKT** for more information.

## 5.2 Composition of identification numbers (support bearings and support bearing units for precision ball screws)

### Support bearings for precision ball screws

### Support bearing units for precision ball screws

## 5. Support bearings and support bearing units for precision ball screws

### 5.3 Tolerance of support bearings for precision ball screws

The support bearings for precision ball screws are manufactured to specific **JTEKT** standards suitable for

the requirements of precision ball screws (see **Table 5.3**).

**Table 5.3 Permissible dimensional deviations and limits of support bearings for precision ball screws**

#### (1) Inner ring

Unit :  $\mu\text{m}$

Nominal bore diameter $d$ (mm)		Single plane mean bore diameter deviation $\Delta d_{mp}$				Single bore diameter deviation $\Delta d_s$				Single inner ring width deviation $\Delta B_s$		Inner ring width variation $V_{B_s}$		$K_{ia}$		Perpendicularity of inner ring face with respect to the bore $S_d$		$S_{ia}$	
		Class 5Z		Class 4Z		Class 5Z		Class 4Z		Classes 5Z, 4Z		Class 5Z	Class 4Z	Class 5Z	Class 4Z	Class 5Z	Class 4Z	Class 5Z	Class 4Z
over	up to	upper	lower	upper	lower	upper	lower	upper	lower	upper	lower	max.		max.		max.		max.	
10	18	0	-5	0	-4	0	-5	0	-4	0	-80	5	2.5	4	2.5	7	3	5	3
18	30	0	-6	0	-5	0	-6	0	-5	0	-120	5	2.5	4	3	8	4	5	3
30	50	0	-8	0	-6	0	-8	0	-6	0	-120	5	3	5	4	8	4	6	3
50	80	0	-9	0	-7	0	-9	0	-7	0	-150	6	4	5	4	8	5	7	4

$K_{ia}$  : Radial runout of assembled bearing inner ring

$S_{ia}$  : Axial runout of assembled bearing inner ring

#### (2) Outer ring

Unit :  $\mu\text{m}$

Nominal outside diameter $D$ (mm)		Single plane mean outside diameter deviation $\Delta D_{mp}$				Single outside diameter deviation $\Delta D_s$				Deviation of a single outer ring width $\Delta C_s$		Ring width variation $V_{C_s}$		$K_{ea}$		$S_D$		$S_{ea}$	
		Class 5Z		Class 4Z		Class 5Z		Class 4Z		Classes 5Z, 4Z		Class 5Z	Class 4Z	Class 5Z	Class 4Z	Class 5Z	Class 4Z	Class 5Z	Class 4Z
over	up to	upper	lower	upper	lower	upper	lower	upper	lower	upper	lower	max.		max.		max.		max.	
30	50	0	-7	0	-6	0	-7	0	-6	Same as tolerance $\Delta B_s$ , $d$ being that of the same bearing.		5	2.5	7	5	8	4	Same as tolerance $S_{ia}$ , $d$ being that of the same bearing.	
50	80	0	-9	0	-7	0	-9	0	-7			6	3	8	5	8	4		
80	120	0	-10	0	-8	0	-10	0	-8			8	4	10	6	9	5		

$K_{ea}$  : Radial runout of assembled bearing outer ring

$S_D$  : Perpendicularity of outer ring surface with respect to the face

$S_{ea}$  : Axial runout of assembled bearing outer ring

### 5.4 Axial load and displacement (support bearings for precision ball screws)

(Matched pair, standard preload)

(Comparison of number of bearing rows)

**Fig. 5.4 Relationship between axial load and displacement (support bearings for precision ball screws)**

5. Support bearings and support bearing units for precision ball screws

SAC0000, SAC00000 series

# 1. Oil / air lubricator

## 1.1 Oil / air lubrication

Oil / air is a new method of lubrication, which was developed to prevent atmospheric contamination caused by oil mist leakage, a phenomenon caused by the high speed of the spindles of machine tools combined with oil mist lubrication.

In oil / air lubrication, an extremely small quantity of oil is supplied and sprayed by air pressure directly into the bearings.

JTEKT has produced an oil / air lubricator and an air cleaning unit, for use as a lubrication system.

### 1) Features of oil / air lubrication

- ① Ensures a low level of temperature increase and power loss of bearing and enables a high rotation speed.  
Supplies the necessary quantity of oil to each bearing in a reliable manner.
- ② High reliability.  
Since new oil is constantly supplied to bearings, the user does not need to be concerned about the service life of the lubrication oil.  
Furthermore, compressed air, which increases the internal pressure of the spindle, is effective in preventing dust or cutting fluid from entering from outside.
- ③ No atmospheric contamination.  
A small quantity of oil flows on the surfaces of piping walls controlled by compressed air. This mechanism eliminates atmospheric contamination caused by oil mist leakage from oil mist lubrication.

### 2) System diagram of oil / air lubrication

Fig. 1.1 System diagram of oil / air lubrication

### 3) Example of connections of oil / air lubrication system

Fig. 1.2 Example of connections of oil / air lubrication systems

## 1.2 Oil / air lubricator

### 1) Features of KOYO oil / air lubricator

- ① Lubrication (discharge) intervals can be set to desired values.  
The lubricator allows adjustment of lubrication (discharge) intervals from 1 to 99 minutes so that optimum settings for lubrication (discharge) intervals can be selected.  
A lock mechanism is provided.
- ② A solenoid valve used to stop air flow is fitted.  
It is included with the standard accessories.  
The valve stops air flow when the machine main unit stops. This eliminates the need for valve operation when shutting down the machine when not in use.
- ③ Oil can be discharged continuously by manual operation.  
Before starting oil / air lubricator, the air in the piping must be discharged (air bleed).  
The lubricator has a circuit built in that allows a single or a successive 11 round oil discharge by manual operation.
- ④ A unique safety device is built in.  
A level switch is attached to the oil tank, and pressure switches are attached to main oil and air pipes.  
In the event of failure of the lubricator, the location of the failure is indicated by a lamp. In addition, an abnormality signal can be output from the abnormality signal contact points (EMG NO-EMGCOM and EMG NC-EMGCOM terminals on the side of the controller).

■ KOYO oil / air lubricator

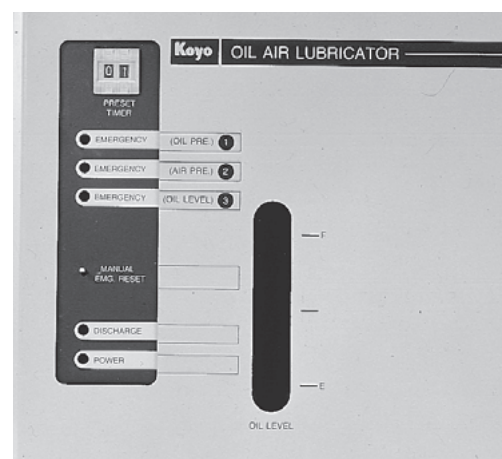

■ KOYO mixing valve

Discharges a small quantity of oil at a fixed rate into the compressed air flow for oil / air lubrication.

■ Controller side view

■ Controller front view

2) Model number of oil / air lubricator (including mixing valve)

Table 1. 1 Symbols of mixing valves and oil discharge quantity

Symbol of mixing valve	Oil discharge quantity (mL/stroke)
A	0.01
B	0.03
C	0.05
D	0.10

For the discharge intervals of the oil / air, refer to Supplementary table 6 on page 219.

\*1) The standard number of oil discharge ports is 5. As it is changeable, specify according to need. The number of maximum available ports is 8 per block.

3) Outline drawing and specifications of oil / air lubricator

Table 1. 2 Specifications

Item	Specification
Supply voltage	AC100V, 50 / 60Hz
Power consumption	With pump in operation : approx. 20W Pump not in operation : approx. 12W
Service air pressure	0.3-0.5 MPa
Viscosity of oil used	10-100mm <sup>2</sup> /s
Lubrication (discharge) intervals	Any desired value between 1 and 99 minutes in one-minute intervals
Tank capacity	1.8L (effective oil quantity : 1.4L)
Capacity of abnormality signal contact points	Contact point a : (EMG NO) 250V AC, 5A 30V DC, 5A Contact point b : (EMG NC) 250V AC, 2A 30V DC, 3A
Mass (refer.)	15 kg

[ Note ] AC200V is also available. Consult JTEKT.

4) Outline drawing and specifications of mixing valve

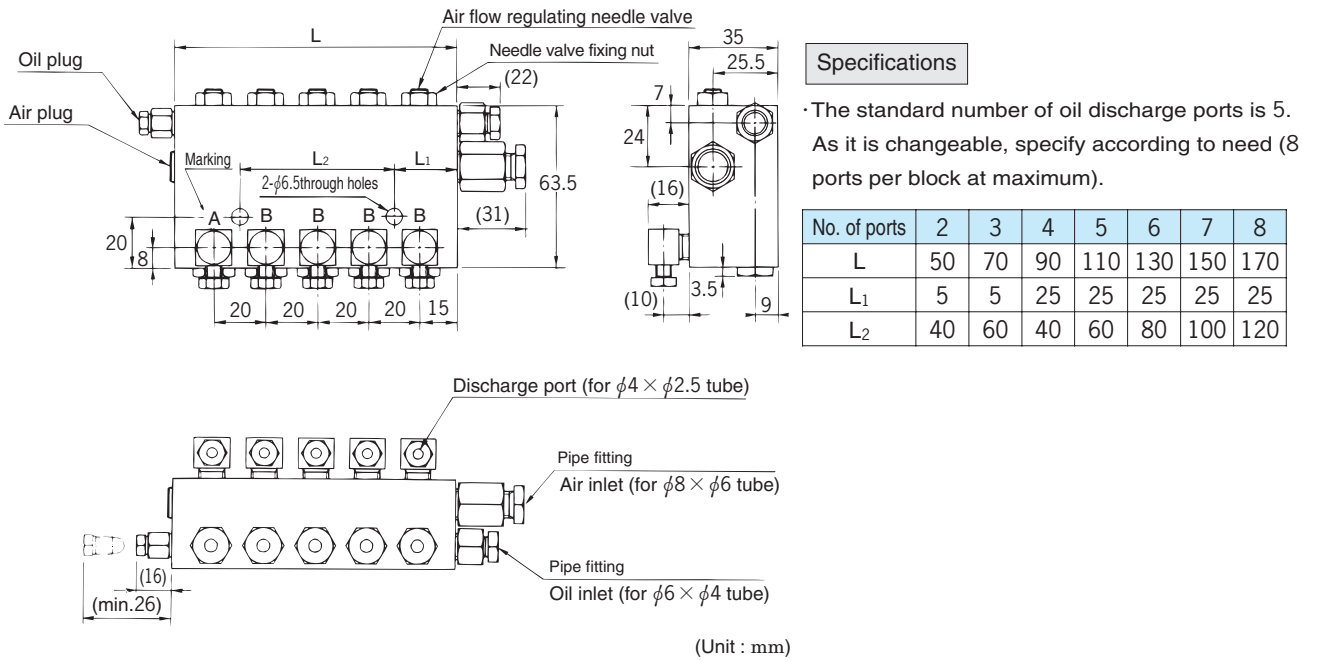

Fig. 1. 4 Outline drawing of KOYO mixing valve (example of 1A4B-1)

## 2. Air cleaning unit

Clean, dry air is required for oil / air lubrication, pneumatic bearings, etc.

**JTEKT** has developed and commercialized the air cleaning unit KAU05, a compact unit consisting of filters, an air dryer, mist separators, and other parts.

This unit efficiently and effectively removes moisture, oil, dust, etc. contained in compressed air.

### 1) Features of KOYO air cleaning units

- ① Removes moisture efficiently by refrigerated air dryer.
- ② Its micro-mist separator removes oil content 99.999 9% and solid foreign matter 0.01 $\mu$ m or greater in particle size.
- ③ Contains a differential pressure detection switch, which indicates clogging of filter.

In addition, an output signal is obtained from terminals attached on the differential pressure detection switch.

### 3) Outline drawing and specifications of air cleaning unit

**Fig. 2. 2 Outline drawing of KOYO air cleaning unit**

**Table 2. 1 Specifications of KOYO air cleaning unit KAU05**

Item	Specification
Treatment air flow rate	0.52/0.57 m <sup>3</sup> /min
Inlet air pressure	0.7 MPa
Maximum temperature of inlet air	50 °C
Main line filter	3 to 50 μm (95%-arresting particle size)
Mist separator	0.3 μm (95%-arresting particle size)
Micro-mist separator	0.01 μm (95%-arresting particle size)
Oil content separation efficiency	99.999 9%
Solid substance separation efficiency	100% if 0.01 μm or greater
Supply voltage	Single-phase 100 V AC (50/60 Hz)*
Power consumption	180/202 W (50/60 Hz) (at 100 V)
Mass (refer.)	26 kg

\*AC 200V is also available.

## III. Handling of Bearings

---

<b>Contents</b>	<b>Page</b>
1. Handling and mounting of bearings .....	<b>192</b>

## 1. Handling and mounting of bearings

### 1.1 Handling precautions of bearings

#### 1.1.1 Handling of bearings

Since ball & roller bearings are made to a higher precision than general mechanical parts, they should be handled carefully.

- ① Maintain bearings and their surroundings in a clean condition.
- ② Handle with care.  
A severe shock to a bearing by rough handling may result in damage such as flaws, nicks and chipping.
- ③ Use correct handling tools.
- ④ Exercise care for rust prevention of bearings.  
Avoid handling and storing them in a highly humid atmosphere.
- ⑤ Bearing should be handled by an experienced person.
- ⑥ Standard operating procedure for handling bearings should be established.
  - Storage of bearings
  - Cleaning of bearings and their peripheral parts
  - Inspection of dimensions and finish of peripheral parts of bearings
  - Mounting
  - Dismounting
  - Inspection after mounting
  - Maintenance and inspection
  - Replenishment of lubricant

#### 1.1.2 Storage of bearings

Bearings are shipped after a high-quality anticorrosive oil is applied to them followed by a suitable wrapping and packing.

Their quality is guaranteed as long as the wrapping and packing are not damaged.

Bearing, if they are to be stored for a long time, should be stored on a shelf at least 30cm from the ground at 65% or less humidity at a temperature of around 20°C. Avoid direct exposure to sunlight. Keep bearings at a distance from walls.

### 1.2 Mounting of bearings

The mounting condition of the bearings affects the accuracy, performance and life of machines.

To optimize the performance of the bearings, it is necessary to strictly follow the procedure and instructions to mount them.

The procedure for mounting the bearings is shown in **Fig. 1. 1**.

In this section, a general procedure for mounting the bearings is described in accordance with the workflow shown in **Fig. 1. 1**.

**Fig. 1. 1 Mounting workflow**

#### 1.2.1 Checking dimensions of peripheral parts of bearings

Before mounting the bearing, clean the shaft, housing, spacer, etc. Ensure that the inside of the housing is absolutely free from any residual wrapping material (SiC, Al<sub>2</sub>O<sub>3</sub>, etc.), molding sand, or chips.

Next, inspect other parts. Check that the dimensions, shapes and roughness are as shown in the drawing, and there is no flaw, burr or barb. Measure the bearing diameter and the bore diameter of the housing at several positions as shown in **Figs. 1. 2** and **1. 3**, and confirm that the fitting is made correctly.

Record the measured values of these parts along with the inspection number of the bearing to be mounted.

**Fig. 1. 2 Measuring positions of shaft diameter**

**Fig. 1. 3 Measuring positions of housing bore diameter**

Besides, pay attention to the fillet radii and the squareness of the shoulders of the shaft and housing. (See **Fig. 1. 4** on page 193.)

For the tolerances for the shaft diameters and the bore diameters of the housing, refer to **Figs. 6. 2** and **6. 3** of "**6. Rigidity and preload of bearings**".

Also, for the accuracy of the shaft and housing as well as the fillet radii, refer to "**9. Designing peripheral parts of bearings**".

Fig. 1. 4 Points for checking the accuracy

### 1. 2. 2 Cleaning bearings

After preparing the parts necessary for mounting the bearings, unwrap the bearings just before starting to mount them.

Anticorrosive oil is applied to the bearings to prevent corrosion. After unwrapping the bearings, clean them

to remove the anticorrosive oil following the procedure shown in Fig. 1. 5.

After cleaning, degrease and dry the bearings. Then, seal grease (in case of grease lubrication) and mount the bearings.

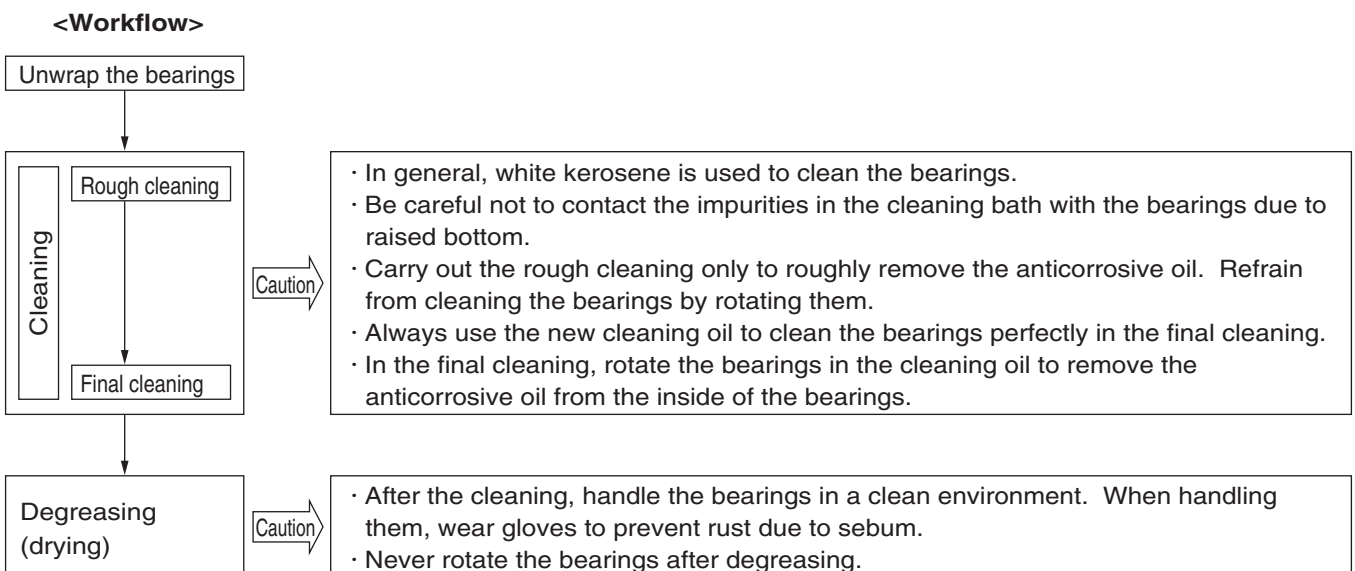

Fig. 1. 5 Cleaning workflow

1. 2. 3 Mounting bearings

The preparation before mounting the bearings varies depending on the bearing types and lubrication as shown in Fig. 1. 6.

For details, see Fig. 1. 6 to mount the bearings.

In case of the angular contact ball bearings, the fitting mark is indicated on the outside surface of the bearing (see page 54). Mount the bearing in the correct direction referring to the fitting mark.

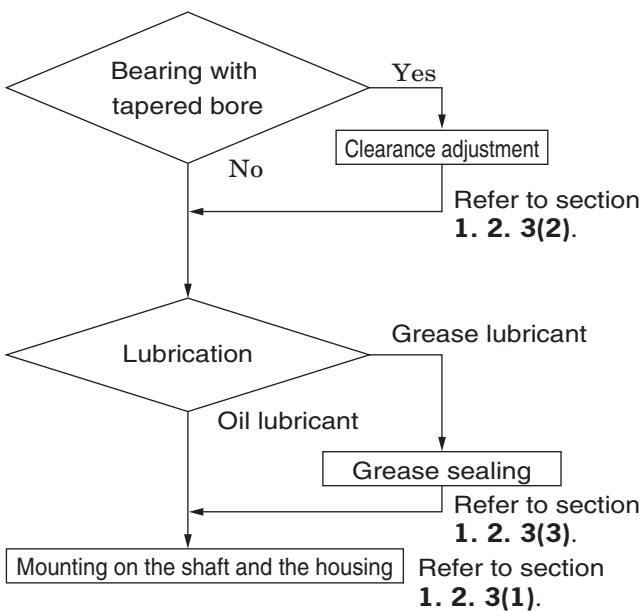

Fig. 1. 6 Preparation before mounting

1. 2. 3(1) Mounting on shaft and housing

① Bearing mounting

Mounting method of the bearings differs depending on types and fitting conditions.

In case of the bearings for machine tool spindles, the inner ring is usually rotated. Therefore, the interference fit is applied for the inner rings, and the clearance fit is applied for the outer rings.

As a method of interference fit, the shrinkage fit is usually applied for the cylindrical bore bearings. In case of the bearings with tapered bore, the inner ring is press fitted in the taper shaft. In this case, the bearing internal clearance needs to be adjusted as described in section 1.2.3(2) beforehand, because it is necessary to control the radial internal clearance after fitting.

The clearance fit is used to fit the outer ring in the housing. To facilitate the mounting, the housing is heated to expand the bore diameter before mounting the bearing.

The bearing before mounting, which is used for oil

lubrication, is very susceptible to flaws, because it is cleaned and degreased and is in metallic contact with a rolling element and raceway. To protect the raceway during the mounting, it is recommended to apply a small quantity of oil used for the machine to be mounted inside the bearing.

● Shrinkage fit

Heat the bearing assembly or inner ring on an induction heater or hot plate to induce expansion before mounting it onto a shaft.

If this method is used, no force is applied to the bearing and operation is carried out in a short time.

When a hot plate is used to heat up a bearing assembly, the use of a jig as shown in Fig. 1. 7 enables efficient heating of the inner ring.

Fig. 1. 7 Inner ring heating jig

Specify the heating temperature of the bearing in accordance with the size and the required expansion, referring to Fig. 1. 8. Specify the temperature about 20 to 30°C higher than the required temperature, taking into consideration the temperature to be reduced during the operation.

However, never heat the bearing up to 120°C or more.

After mounting the bearing, shrinkage will occur in the width as the bearing cools off. Therefore, fit the inner ring and the shoulder firmly using a locknut to prevent clearance between them.

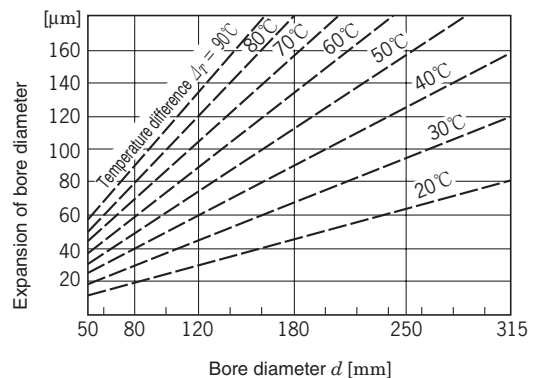

Fig. 1. 8 Heating temperature and expansion of inner rings

●Press fit

Be sure to use the specific jig to mount the inner ring to the shaft and the outer ring to the housing. When press fitting the inner ring and the outer ring, hold only the inner ring and the outer ring, respectively, and apply gently uniform pressure to the whole circumference surface.

Never mount the rings using hammer.

To facilitate the mounting, it is recommended to apply a small quantity of lubricant to the shaft or housing before press fitting.

**Fig. 1. 9 Press fitting by pressing machine**

**Fig. 1. 10 Example of press fitting jig**

**[ Reference ] Force is necessary to press fit or remove bearings**

The force necessary to press fit or remove inner rings of bearings differs depending on the finish of shafts and how much interference the bearings allow. The standard values can be obtained by using the following equations.

(In the case of solid shafts)

$$K_a = 9.8 f_k \cdot \Delta_{d_{eff}} \cdot B \left( 1 - \frac{d^2}{D_i^2} \right) \times 10^3 \dots\dots\dots(1. 1)$$

(In the case of hollow shafts)

$$K_a = 9.8 f_k \cdot \Delta_{d_{eff}} \cdot B \frac{\left( 1 - \frac{d^2}{D_i^2} \right) \left( 1 - \frac{d_0^2}{d^2} \right)}{\left( 1 - \frac{d_0^2}{D_i^2} \right)} \times 10^3 \dots\dots\dots(1. 2)$$

Where:

$K_a$  : force necessary for press fit or removal N

$\Delta_{d_{eff}}$  : effective interference mm

$f_k$  : resistance coefficient

[ Coefficient taking into consideration friction between shafts and inner rings ... refer to the table below. ]

$B$  : nominal inner ring width mm

$d$  : nominal inner ring bore diameter mm

$D_i$  : average outside diameter of inner ring mm

$d_0$  : hollow shaft bore diameter mm

**Value of resistance coefficient  $f_k$**

Conditions	$f_k$
· Press fitting bearings on to cylindrical shafts	4
· Removing bearings from cylindrical shafts	6
· Press fitting bearings on to tapered shafts or tapered sleeves	5.5
· Removing bearings from tapered shafts or tapered sleeves	4.5
· Press fitting tapered sleeves between shafts and bearings	10
· Removing tapered sleeves from the space between shafts and bearings	11

#### ② Tightening of bearings

##### ●Tightening of inner ring

As a way of fixing the inner ring to a shaft, a locknut is usually used. **Fig. 1. 11** shows an example of fixing an inner ring using a locknut.

**Fig. 1. 11 Example of fixing on inner ring using a locknut**

As a clearance is present between thread of the locknut and that of the shaft, fixing the inner ring by using a locknut results in the center of the locknut deviating from the center of the shaft. This deviation in turn causes inclination of the inner ring or bending of the shaft.

As a result, the running accuracy of the shaft is decreased or an abnormal temperature increase is experienced due to the high load applied to the bearing (see **Fig. 1. 12**).

To settle this problem, positioning (centering) of the locknut is necessary after tightening.

**Fig. 1. 12 relationship between shaft radial runout and temperature increase of the outer ring caused by the faulty positioning of the inner ring**

Furthermore, the axial force generated by tightening the locknut leads to compressive strain of the inner ring and inner ring spacer, which in the case of position preloading, influence the amount of preload applied to the bearing.

For those applications which are considerably affected by preload, such as a high-speed spindle, this compressive strain should be taken into consideration. Consideration to other types of bearing supports are the inclination of inner rings, bending of shafts, and axial forces. In cases where a interference fit sleeve is used to fix a bearing, the tolerance of the sleeve is of

vital importance since positioning becomes difficult once the bearing is fitted.

Tightening forces (shaft forces) of the locknuts or sleeves used to fix the inner rings are indicated as standard values in the bearing dimension table.

Note that if the interference of inner ring is large and the number of bearing rows is large, the press fitting force also becomes large.

##### ●Tightening of outer rings

Outer rings are fixed to the housing usually by means of a retaining plate.

The retaining plate is fastened to the housing with several bolts. Inadvertent fastening of the retaining plate, however, may result in an inclination and / or deformation of the outer ring.

If inclination and / or deformation occurs in the outer ring, the rolling elements and the cage cannot rotate properly, possibly causing unusual noise generation.

In order to prevent this, it is necessary to tighten the retaining plate fastening bolts with an even torque in diagonal sequence. The fastening bolts should not be fastened individually to the final torque, but in a step-by-step sequence (see **Fig. 1. 13**).

**Fig. 1. 13 Raceway roundness variations with respect to the various fastening method**

A slight interference is provided between the housing and retaining plate to hold the outer ring firmly.

If variations on the interference exist on the circumference due to poor tolerance of the retaining plate or housing, fastening the retaining plate may cause inclination of the outer ring.

Therefore, sufficient care should be taken to ensure tolerance of the retaining plate and housing.

For the interference between the housing and retaining plate, refer to the dimension table for each bearing.

## 1. 2. 3(2) Adjusting of clearance

In case of the cylindrical roller bearing with tapered bore, it is necessary to adjust the dimension of the spacer to adjust the radial clearance of the bearing.

The adjustment is made as follows.

- (1) Lightly apply low-viscosity oil (kerosene, etc.) to the taper part of the shaft and fit slightly the inner ring of the cylindrical roller bearing into the shaft (Fig. 1. 14).

Fig. 1. 14 Temporary mounting of inner ring

- (2) Using a block gauge, measure the distance between the end face of the inner ring and that of the shoulder (Fig. 1. 15).

Fig. 1. 15 Width of spacer

- (3) Temporarily adjust the width of the spacer. Adjust the width of the spacer to the distance between the end face of the inner ring and that of the shoulder as measured in step (2). It is recommendable to make the outside diameter of the spacer larger than the diameter of the shaft shoulder to facilitate the pulling-out (Useful when pulling out the inner ring).

**Note:** The parallelism of lateral side of the spacer must be 0.001mm or less.

- (4) After degreasing the outside surface and the bore, fit the temporarily adjusted spacer and mount the inner ring onto the shaft. Be careful not to make clearance between the end face of the spacer and that of the inner ring and clearance between the end face of the spacer and that of the shaft shoulder (Fig. 1. 16).

Fig. 1. 16 Mounting of spacer

- (5) Place the dial gauge on the outside surface of the outer ring, and move the outer ring upward and downward on the axial line of the dial gauge needle to measure the residual radial internal clearance (Fig. 1. 17).

- (6) After measurement, pull the bearing and the spacer out of the shaft.

Never hit the bearing to pull it out (Hit gently the end face of the spacer of large outside diameter).

- (7) Based on the radial internal clearance measured in step (5), use the equation shown below to calculate the adjustment value of the inner ring to obtain the desired residual radial internal clearance.

In case of taper 1/12,

$$\text{Adjustment value } \Delta_A = (R_{sa} - R_{sb} - R_{sc}) \times 12 / K$$

Where:

$R_{sa}$ : measured radial internal clearance ..... the value measured in step (5)

$R_{sb}$ : desired radial internal clearance

$R_{sc}$ : contraction of the outer ring raceway due to fitting (0 in case of clearance fit)

$K$ : expansion coefficient of the inner ring raceway due to press fitting

Formula to calculate  $R_{sc}$

$$R_{sc} = \Delta_{Deff} \frac{D_e}{D} \cdot \frac{\left(1 - \frac{D^2}{D_h^2}\right)}{\left(1 - \frac{D_e^2}{D_h^2}\right)}$$

Formula to calculate  $K$

$$K = \frac{d}{D_i} \frac{\left(1 - \frac{d_0^2}{d^2}\right)}{\left(1 - \frac{d_0^2}{D_i^2}\right)}$$

Where:

$\Delta_{Deff}$ : effective interference of outer ring

$D_h$ : outside diameter of housing

$D_e$ : outer ring raceway contact diameter

[ ball bearing .....  $D_e \cong 0.2 (4D + d)$   
roller bearing .....  $D_e \cong 0.25 (3D + d)$

$D$ : nominal outer ring outside diameter

$d$ : nominal inner ring bore diameter (shaft diameter)

$d_0$ : bore diameter of hollow shaft

$D_i$ : inner ring raceway contact diameter

[ ball bearing .....  $D_i \cong 0.2 (D + 4d)$   
roller bearing .....  $D_i \cong 0.25 (D + 3d)$

Fig. 1. 17 Measurement of residual radial clearance

(8) Adjust the width of the spacer.

The width of the spacer must be the value temporarily adjusted minus the adjustment value calculated in step (7).

**Note:** The parallelism of lateral side of the spacer must be 0.001 mm or less.

(9) After cleaning, mount the bearing and the spacer onto the shaft.

Push inner ring sufficiently so that the end face of the spacer and that of the inner ring as well as the end face of the spacer and that of the shaft shoulder contact each other completely (**Fig. 1. 18**).

**Fig. 1. 18 Mounting of bearing**

(10) As in step (5), check the residual radial internal clearance of the bearing.

If the desired value of the radial internal clearance is not obtained, return to step (7) and make adjustment again.

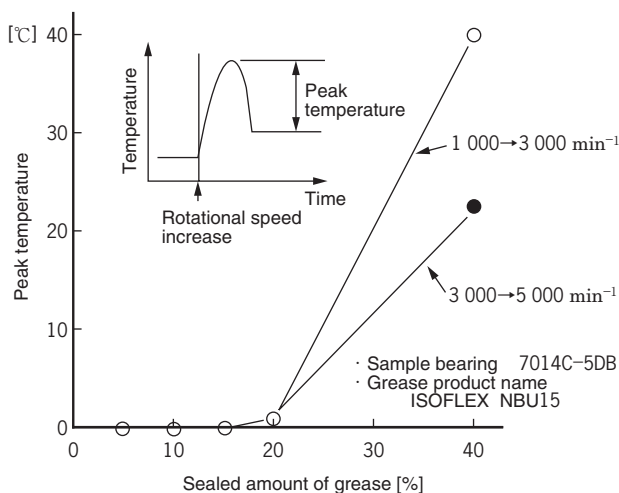

(11) After checking that the desired value of the radial internal clearance is obtained in step (10), pull the bearing and spacer out of the shaft temporarily to clean and degrease them. In case of grease lubrication, seal them with the specified amount of grease, and then reassemble them.

#### 1. 2. 3(3) Grease sealing

If the sealed amount of grease or the sealing method is not appropriate, overheating or instability (**Fig. 1. 19**) may result during breaking-in, and an extended time of breaking-in may become necessary.

Therefore, be sure to seal the bearing with an appropriate amount of grease in correct manner.

Sealing method of grease is described below.

**Fig. 1. 19 Relationship between sealed amount of grease and peak temperature**

#### ① Preparation before sealing

- Clean and degrease the bearing. And check that there is no stain of anticorrosive oil or impurity on the interspace and outer surfaces of the bearing.
- An appropriate amount of grease must be applied uniformly to the specified locations in the bearing. To apply grease, it is recommended to use a specific tool with measuring gauge, which has a nozzle tip.
- The tool used to apply grease also has to be cleaned off and degreased.
- Before applying grease, check the amount of grease to be sealed. The amount should be 10 to 15% of the space capacity of the bearing. (The space capacity of each bearing and the sealed amount of grease are shown in the bearing dimension table.)

#### ② Method for grease sealing

Grease must be applied uniformly to the bearing raceway surface and the retainer guide as shown in **Fig. 1. 20**.

After applying grease, manually rotate the bearing to let the grease spread all over the inside of the bearing.

Also, after application of grease, be careful not to let impurities dust to the bearing.

**Fig. 1. 20 Grease sealing points**

## 1. 2. 4 Check after mounting bearings

### 1. 2. 4(1) Checking of preload

Preload of the bearing affects its rigidity and heat generation. If the preload is inadequate, not only the standard performance is not obtained, but also the life span is shortened and seizure results.

Therefore, it is important to check that the specified preload is applied to the bearing after completing the mounting of the bearing.

In this section, the following methods for checking the preload, which are generally used, are described.

#### ① Check using the starting torque

If the preload of the bearing becomes large, the starting torque also tends to increase. Therefore, the preload can be checked by measuring the starting torque value.

Wind the thread on the shaft or the outer ring and fix it. By pulling the thread tangentially, measure the tension of the thread when the bearing starts to rotate using a tension gauge, etc. After obtaining the starting torque, the preload can be presumed referring to the correlation between the starting torque and the preload.

The starting torque can be measured easily. However, in case of the bearings used with low preload (e.g. angular contact ball bearing used as a spindle), the measurement error can be large because the starting torque is small. This method is recommendable when using the ball screw support bearings by applying heavy preload to them.

Note that it is necessary to standardize the sampling and measurement conditions because the condition of the lubricant and pulling speed affect the measurement result.

#### ② Check using the axial rigidity

The preload is confirmed referring to the correlation between the shaft end axial deviation measured by applying the axial load to the shaft end, and the axial rigidity and the preload.

This method is not recommendable when using a main shaft of high rigidity because the deviation is very small.

To use this method, a large-sized facility such as a load applying device is necessary. Also, it is necessary to standardize the sampling and measurement conditions because the parts other than the bearing have elastic deformability.

#### ③ Check using the proper vibrations

The preload is confirmed referring to the correlation between the spring constant of the bearing and the preload.

This method guarantees accuracy and repeatability of measured values.

However, the fixing method has to be meticulously inspected and standardized because the results are affected by the fixing method.

### 1. 2. 4(2) Breaking-in

In case of the bearings for grease lubrication, after installation of a bearing, problems are likely to occur due to rapid temperature rise caused by the immediate application of the maximum specified rotational speed. Therefore, breaking-in of the bearing is recommended, in which rotational speed is increased gradually.

Specifically, roller bearings require adequate breaking-in.

Fig. 1. 21 shows an example of breaking-in.

**Fig. 1. 21 Example of breaking-in**  
(In case of 5 000 min<sup>-1</sup> max. speed)

If carrying out the break-in, after increasing the rotational speed, wait until the temperature of the bearing stops to increase or starts to decrease. Then, increase the rotational speed further.

Never increase the rotational speed when the temperature of the bearing is increasing.

The higher the temperature of the bearing becomes, the faster the grease deteriorates. Therefore, it is important to monitor the temperature during the breaking-in. When the temperature reaches a certain level, stop the operation temporarily. After the bearing cools off, resume the break-in starting from the rotational speed at which the operation was stopped or lower.

If the temperature is measured on the outside surface of the housing or retaining plate, the temperature at which the operation should be stopped is the room temperature plus 30 to 40°C (Supposing that the room temperature is 15 to 25°C).

The break-in is not required for the bearings lubricated with oil. However, if the bearings are used for the first time or after stored for an extended period of time, it is recommended to carry out the break-in because an abrupt increase of temperature may be expected due to the oil remaining in the lubrication duct and the inside of the bearing (excessive oil quantity).

#### 1. 2. 4(3) Trial run and inspection

A trial run and inspection are carried out when bearings have been mounted, in order to check whether the mounting is adequate.

In the case of a small spindle, the rotation condition is examined initially by rotating it manually. After confirming that the below conditions do not exist, a further inspection is carried out by a powered run.

- Unsmoothness.....Possible causes are mixing of foreign matter, flaw in rolling surfaces, etc.  
Grease used in grease lubrication may cause a phenomenon of unsmoothness at the initial stage.  
In such cases, unsmoothness disappears after breaking-in.
- Excessive torque.....Possible causes are friction in the sealing device, insufficient clearance, etc.
- Uneven rotational.....Possible causes are defective mounting, and / or errors in mounting dimensions.

In the case of a large spindle that cannot be rotated manually, start it under unloaded condition and immediately after starting, turn the power off and allow to coast.

After verifying that the shaft is free of abnormal vibration or noise and rotates smoothly, proceed to powered run.

Powered run should be started with no load applied and at a low speed, before being increased gradually to a given condition.

Noise, temperature increase, and vibration are principal judging factors in powered run and inspection. If a faulty condition such as shown in **Tables 1. 1** and **1. 2** (page 200 and 201) occurs, conduct a further inspection immediately.

In some cases, it is necessary to remove the bearing for inspection.

**Table 1. 1 Bearing noises, causes, and countermeasures**

Noise types		Causes	Countermeasures
Cyclic	Flaw noise (similar to noise when punching a rivet <sup>1)</sup> ) Brinelling noise (unclear siren-line noise <sup>1)</sup> )	Flaw on raceway Brinelling on raceway	Improve mounting procedure, cleaning method and rust preventive method. Replace bearing.
	Flaking noise (similar to a large hammering noise <sup>1)</sup> )	Flaking on raceway	
Not cyclic	Dirt noise (an irregular sandy noise <sup>1)</sup> )	Insertion of foreign matter	Improve cleaning method, sealing device. Use clean lubricant. Replace bearing.
	Flaw noise, flaking noise	Flaws and flaking on rolling elements	Replace bearing.
	Squeak noise (often heard in cylindrical roller bearing with grease lubrication, especially in winter or at low temperature)	If noise is caused by improper lubrication, a proper lubricant should be selected. In general, however, serious damage will not be caused by an improper lubricant if used continuously.	
Others	Abnormally large metallic sound	Abnormal load Incorrect mounting Insufficient amount of or improper lubricant	Review fitting, clearance. Adjust preload. Improve accuracy in processing and mounting shafts and housings. Improve sealing device. Refill lubricant. Select proper lubricant.

[ Note ] 1) In case of slow or medium rotation.

**Table 1. 2 Causes and countermeasures for abnormal temperature rise**

Causes	Countermeasures
Too much lubricant	Reduce lubricant amount
Insufficient lubricant	Refill lubricant
Improper lubricant	Select proper lubricant
Abnormal load	Review fitting and clearance conditions and adjust preload
Improper mounting (excessive friction)	Improve accuracy in processing and mounting shaft and housing. Review fitting. Improve sealing device.

Normally, listening rods are employed for bearing noise inspections. The device, which detects abnormalities through sound vibration, and the system, which utilizes acoustic emission for abnormality detection, are useful for more precise inspection.

In general, bearing temperature can be estimated from housing temperature, but the most accurate method is to measure the temperature of outer rings directly via lubrication holes.

Normally, bearing temperature begins to rise gradually when operation is just starting; and, unless the bearing has some abnormality, the temperature stabilizes within one or two hours.

Therefore, a rapid rise in temperature or unusually high temperature indicates some abnormality.

### 1. 2. 5 Dismounting of bearings

Dismounting a bearing for reuse or identification of causes of failure should be carried out in a careful manner similar to that of when mounted. Care should be taken to avoid damage to the bearing and other parts.

Specifically, when dismantling a bearing involving an interference, the dismantling process of the bearing should be taken into consideration at the designing stage of the shaft and housing.

It is recommended to make a jig for dismantling where appropriate.

## IV . Examples of Bearing Failures

## 1. Bearing failures, causes and countermeasures

It is necessary to carry out the maintenance and inspection to use the machine equipment always in stable conditions.

The bearing is an important part of the machine installation. If the bearing is damaged, the machine may become nonoperating and other inadvertent effects may occur.

Rotation noise, vibrations, temperature and torque are important phenomena to determine the status of the bearing. If any abnormality is perceived in such phenomena, it is necessary to immediately find the cause of the problem and take appropriate measures.

In **Table 1. 1**, bearing failures, possible causes and countermeasures are shown.

**Table 1. 1 Bearing failures, causes and countermeasures**

Phenomena	Causes	Countermeasures	Notes	
Temperature rise	Excessive	Excessively small quantity of lubricant	Check the quantity of the enclosed grease and the oil / air blow. Check that there is no leakage in the oil / air pipe.	Usually this phenomenon is accompanied by metallic noise. Grease may be deteriorated or leaking if this phenomenon occurs during normal operation in case of grease lubrication.
		Excessively large quantity of lubricant	Check the quantity of the enclosed grease and the oil / air blow.	In case of grease lubrication, the breaking-in may be insufficient.
		Angular contact ball bearing: excessive preload Cylindrical roller bearing: excessive negative clearance	Check the bearing axial clearance and mounting conditions.	Refer to case ① (page 205).
		Inadequate mounting precision	Check that there is no misalignment.	If reinstalling the bearing, it is necessary to check the precision of the parts after dismounting it.
		Insufficient cooling	Check the availability of the cooling capacity required.	
		External factors	Check that the belt tension is not excessive, the built-in motor is not heated excessively, and the coupling core is precisely placed.	
		Deterioration of bearing	Replace the bearing.	Usually this phenomenon is accompanied by torque rise.
	Instable	Oil / air lubrication: bad exhaust Grease lubrication: insufficient breaking-in	Check the oil / air exhaust route.	In case of oil / air lubrication, if the oil blows intermittently (irregularly) from the exhaust port, the exhaust (oil drainage) is not carried out correctly.
Noise	Metallic noise	Excessively small quantity of lubricant	Check the quantity of the enclosed grease and the oil / air blow. Check that there is no leakage in the oil / air pipe.	This phenomenon is accompanied by excessive temperature rise. Grease may be deteriorated or leaking if this phenomenon occurs during normal operation in case of grease lubrication.
	Continuous noise	Contact and interference between all rotating parts and all non-rotating parts	Check the conditions of the mounted parts, including the labyrinth.	If this phenomenon occurs during normal operation, it may be the secondary phenomenon of a temporal failure.
		Unbalanced shaft and imprecise rotation	Adjust the shaft balance. Readjust the rotational accuracy.	This phenomenon is accompanied by buzzing noise. If this phenomenon occurs during normal operation, it may be the secondary phenomenon of a temporal failure.
		Rough surface and brinelling of raceway	Replace the bearing in the case of entry of foreign particle, flaking and excessive load.	Refer to cases ② and ③ (page 205 and 206). If there is no measure taken, this phenomenon may occur repeatedly.
	Intermittent noise	Noise of cages, and slippage because of preload leakage	If the preload is excessively small, check the axial clearance and mounting conditions of the bearing.	
Vibrations		Unbalanced shaft	Adjust the shaft balance. Readjust the rotational accuracy.	
		Excessive radial clearance of cylindrical roller bearing	Check the radial clearance of the bearing. Check the mounting conditions.	In case of the bearing with tapered bore, the shaft nut may be loose. Also, the wear may have worsened.
		Rough surface and brinelling of raceway	Replace the bearing in the case of entry of foreign particle, flaking and excessive load.	Refer to cases ② and ③ (page 205 and 206).

## Case ① Excessive bearing preload

### Causes

#### 1) Inadequate fitting

- Excessively large interference fitting of the inner ring  
⇒ Due to the increase of interference of the inner ring and the shaft, the diameter of the raceway expands and the preload increases.
- Excessively small clearance fitting of the outer ring  
⇒ If a temperature difference is generated between the outer ring and the housing, the outer ring is compressed and the diameter of the raceway shrinks, resulting in an increase in preload.

#### 2) Inadequate tightening force of the bearing

- If the tightening force of the inner ring (nut shaft force etc.) is excessively large, the inner ring is deformed in axial direction and the preload increases.

#### 3) Excessive cooling of the housing

- If the outer surface of the housing is excessively cooled, the phenomenon described in item 1) is generated and the preload increases.

#### 4) Failure in constant-pressure preloading and variable preloading system

- If the outer ring cannot be moved smoothly by the constant-pressure preloading and the preload variable spindle, the same phenomenon as in the case of the position preloading is generated, and an excessive preload is applied to the bearing.

Fig. 1.1 Cause of increase in preload

## Case ② Entry of foreign particle

Major foreign particles are as follows.

- Coolant
- Chippings
- Iron chips (housing material)

### Causes

#### 1) Poor sealing performance

If the labyrinth is not adequately configured for use conditions, the sufficient sealing effect is not obtained, and the foreign particles, including coolant, may be trapped in the bearing.

#### 2) Part not cleaned sufficiently

If the parts are not cleaned sufficiently, small burrs and barbs exist, they may fall into the inside of the bearing during the operation.

#### 3) Dirty lubricant

If the oil lubricant is not completely washed out of the pipe, or if the environment for the enclosing grease is not adequate, foreign particles may be trapped in the lubricant and the bearing may be damaged.

Fig. 1.2 Example of biting flaws formed in raceway because of entry of foreign particle

**Case ③ Damage on the raceway surface (nick and flaking)**

**Causes**

**1) Nick**

Nick may be produced on the raceway surface if the main shaft is hit, any excessive load is applied to the bearing because of the clamping and unclamping of the tool, or the bearing is not properly handled.

**Fig. 1. 3 Example of nicks**

**2) Flaking**

As the bearing becomes old, the flaking occurs if the load is applied repeatedly to the raceway surface.

However, even in case of a new bearing, the flaking may occur if an excessive load is applied to the bearing or the oil film is formed insufficiently.

Also, the flaking may be generated by the brinelling (nicks).

**Fig. 1. 4 Example of flaking**

- [ Remarks ]**
- The discharge intervals indicated are reference values supposing that the oil quantity of one discharge is 0.03ml in case of the angular contact ball bearing.
  - If the cylindrical roller bearing is used, suppose that the discharge interval is the same, and the oil quantity of one discharge is 0.01ml.
  - Select the optimal value of the required oil quantity by carrying out the test on the machine referring to the table above, because the optimal value varies depending on the type of the bearing, environment and use conditions.
  - ISO VG22 or VG32 is recommended in case of the main shaft driven by the built-in motor.
